Received April 2, 1997

Multiple bonding of the transition metals is under intense scrutiny.^{1,2} To date, however, most of these studies have been concerned with transition metal complexes exhibiting multiple bonds to the second-row groups 14–16 elements: carbon, nitrogen, and oxygen. By comparison, relatively few reports describe multiple bonding to the heavier congeners of these elements. We have a particular interest in multiple bonding of transition metals to the heavier chalcogens (especially tellurium),^{3,4} and, with this paper, we extend our investigations to titanium and vanadium. These studies include the first structural characterization of multiply bonded titanium and vanadium terminal tellurido complexes.

As with multiply bonded chalcogenido complexes of the transition metals in general, the vast majority of studies concerned with titanium and vanadium have centered on oxo and sulfido derivatives.⁵ Terminal tellurido complexes of these elements are particularly elusive. For example, Piers and Ziegler recently described several attempts to prepare the titanium tellurido complex $\text{Cp}^*_2\text{Ti}(\text{Te})(\text{NC}_5\text{H}_5)$,⁶ rather than yielding a terminal tellurido complex, however, only the bridging tellurido and ditellurido complexes $[\text{Cp}^*_2\text{Ti}]_2(\mu\text{-Te})$ and $\text{Cp}^*_2\text{Ti}(\eta^2\text{-Te}_2)$ were isolated. The inability to isolate the titanium tellurido complex $\text{Cp}^*_2\text{Ti}(\text{Te})(\text{NC}_5\text{H}_5)$ is especially significant in light of the fact that both the zirconium and hafnium tellurido analogues $\text{Cp}^*_2\text{M}(\text{Te})(\text{NC}_5\text{H}_5)$ ($\text{M} = \text{Zr}, \text{Hf}$)^{3a,b} and the titanium oxo and sulfido complexes, $\text{Cp}^*_2\text{Ti}(\text{O})(\text{NC}_5\text{H}_5)$ ⁷ and $\text{Cp}^*_2\text{Ti}(\text{S})(\text{NC}_5\text{H}_5)$,⁸ are known.⁹ The synthesis of a complex containing a multiply bonded $[\text{Ti}=\text{Te}]$ moiety, therefore, presented a challenge. Since macrocyclic ligands (e.g., porphyrin, phthalocyanine, and tetraazaannulene) have proven to be most effective for the isolation of terminal titanium oxo complexes,¹⁰ it was

(9) One of the principal factors responsible for the difficulty in synthesizing $\text{Cp}^*_2\text{Ti}(\text{Te})(\text{NC}_5\text{H}_5)$ is a particularly weak $[\text{Ti}=\text{Te}]$ interaction. For example, Piers and Ziegler^{6b} have calculated the following $M=E$ bond energies: $\text{Cp}_2\text{Ti}=\text{O}$ (143.2 kcal mol⁻¹); $\text{Cp}_2\text{Ti}=\text{Te}$ (61.8 kcal mol⁻¹); $\text{Cp}_2\text{Zr}=\text{Te}$ (88.0 kcal mol⁻¹).

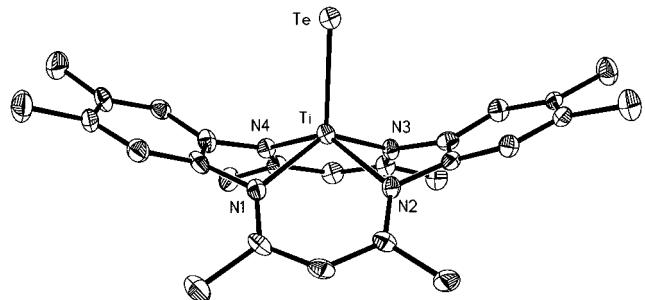

Figure 1. Molecular structure of $[\eta^4\text{-Me}_8\text{taa}]Ti=Te$.

rationalized that such a ligand system could likewise support a $[\text{Ti}=\text{Te}]$ moiety, in a manner similar to our previously reported use of the octamethylbibenzotetraaza[14]annulene dianion to stabilize the group 14 terminal tellurido counterpart $[\eta^4\text{-Me}_8\text{taa}]GeTe$.^{11–13}

Indeed, the titanium tellurido complex $[\eta^4\text{-Me}_8\text{taa}]Ti=Te$ is readily synthesized by the reaction of $[\eta^4\text{-Me}_8\text{taa}]TiCl_2$ ¹⁴ with $(Bu^*\text{Me}_2\text{Si})_2\text{Te}$ ^{15,16} (Scheme 1). The molecular structure of $[\eta^4\text{-Me}_8\text{taa}]Ti=Te$ has been determined by X-ray diffraction,¹⁷ as illustrated in Figure 1, thereby providing evidence for the monomeric nature of the complex and the presence of a terminal tellurido ligand. Of most relevance, the $Ti=Te$ bond length of 2.484(2) Å in $[\eta^4\text{-Me}_8\text{taa}]Ti=Te$ is significantly shorter than all other $Ti=Te$ interactions that have been reported, clearly attesting to the multiply bonded nature of the interaction. Specifically, $Ti=Te$ single bonds are known to span the range 2.62–2.91 Å, with a mean of 2.78 Å.¹⁸

As would be expected, the multiply bonded $[\text{Ti}=\text{Te}]$ moiety is reactive and $[\eta^4\text{-Me}_8\text{taa}]Ti=Te$ is readily converted to the oxo derivative $[\eta^4\text{-Me}_8\text{taa}]Ti=O^{12d}$ upon treatment with either

(16) The synthesis of bridging chalcogenido complexes via metathesis of $M-Cl$ (including $Ti-Cl$ and $V-Cl$) bonds with $(\text{Me}_3\text{Si})_2\text{E}$ ($E = S, Se, Te$) is well preceded. See, for examples: (a) Maué, P. G.; Fenske, D. Z. *Naturforsch.* 1988, 43B, 1213–1218. (b) Fenske, D.; Grissinger, A. Z. *Naturforsch.* 1990, 45B, 1309–1313. (c) Fenske, D.; Grissinger, A.; Loos, M.; Magull, J. Z. *Anorg. Allg. Chem.* 1991, 598/599, 121–128. (d) Fenske, D.; Ohmer, J.; Hachgenei, J.; Merzweiler, K. *Angew. Chem., Int. Ed. Engl.* 1988, 27, 1277–1296.

(17) $[\eta^4\text{-Me}_8\text{taa}]Ti=Te \cdot 1.5(C_6\text{H}_6)$ is monoclinic $P2_1/c$ (no. 14), $a = 9.848(3)$ Å, $b = 24.290(8)$ Å, $c = 14.416(4)$ Å, $\beta = 94.15(2)$ °, $V = 3439(2)$ Å³, $Z = 4$.

Scheme 1

O₂ or N₂O at room temperature (Scheme 1). Furthermore, [η⁴-Me₈taa]Ti=Te reacts with excess Me₃SiCl at room temperature to regenerate [η⁴-Me₈taa]TiCl₂ (Scheme 1).¹⁹

The methodology used to synthesize [η⁴-Me₈taa]Ti=Te is also applicable to its vanadium counterpart [η⁴-Me₈taa]V=Te (Scheme 1). Unlike Schrock's [η⁴-N(CH₂CH₂NSiMe₃)₃]V=Te,²⁰ which is the only other example of a terminal vanadium tellurido complex, [η⁴-Me₈taa]V=Te is sufficiently stable to permit characterization by X-ray diffraction.²¹ Consistent with the presence of a multiple bond, the V=Te bond lengths in the two crystallographically independent molecules [2.433(1) and 2.435(1) Å] are shorter than those in the bridging vanadium tellurido complex [V(CO)₃(dppe)]₂(μ₂-Te) [2.514(3) and 2.522(3) Å].^{22,23}

In addition to the terminal tellurido complexes [η⁴-Me₈taa]M=Te (M = Ti, V), both the titanium and vanadium selenido analogues have been synthesized *via* reactions of [η⁴-Me₈taa]MCl₂ with (Bu¹Me₂Si)₂Se.²⁴ Notably, these complexes are also obtained by the reactions of the oxo derivatives [η⁴-

(18) Structurally characterized complexes with Ti=Te bonds include [(Cp^{Me})₂Ti(μ-Te₂)₂], 2.791(3)–2.799(3) Å;^{18a} (Cp^{Me})₅Ti(μ-Te)₆, 2.622(2)–2.858(2) Å;^{18a} [Cp^{*}₂Ti]₂(μ-Te), 2.697(3)–2.705(3) Å;⁶ Cp^{Me}₂Ti(η²-Te₂), 2.808(3) Å;⁶ Cp^{Me}₂Ti[TeSi(SiMe₃)₃]₂, 2.788(1) Å;^{18b} and Cp₂Ti[TeSi(SiMe₃)₃](PMe₃), 2.879(3)–2.912(3) Å.^{18b} (a) Fenske, D.; Grissinger, A. Z. Naturforsch. **1990**, 45B, 1309–1313. (b) Christou, V.; Wuller, S. P.; Arnold, J. J. Am. Chem. Soc. **1993**, 115, 10545–10552.

(19) The ability of Me₃SiCl to regenerate [η⁴-Me₈taa]TiCl₂, and thereby effect the reverse of the reaction between (Bu¹Me₂Si)₂E and [η⁴-Me₈taa]TiCl₂, is presumably the result of the instability of (Me₃Si)₂E compared to (Bu¹Me₂Si)₂E. For example, (Me₃Si)₂Te experiences serious decomposition even in the dark under Ar at –20 °C. See ref 15.

(23) Other complexes for which V=Te bond lengths have been determined include V[TeSi(SiMe₃)₃]₄, *d*(V–Te) = 2.550(3)–2.570(3) Å;^{23a} [(Me₃Si)₂N]₂VTe[Si(SiMe₃)₃], *d*(V–Te) = 2.6758(9) Å;^{23b} and [(Me₃Si)₂N]₂VTeSiPh₃, *d*(V–Te) = 2.675(2) Å.^{23b} (a) Gerlach, C. P.; Wuller, S. P.; Arnold, J. J. *J. Chem. Soc., Chem. Commun.* **1996**, 2565–2566. (b) Gerlach, C. P.; Arnold, J. *Inorg. Chem.* **1996**, 35, 5770–5780.

(24) (Bu¹Me₂Si)₂Se is prepared analogously to (Bu¹Me₂Si)₂Te. See ref 12.

Me₈taa]Ti=O^{12d} and [η⁴-Me₈taa]V=O¹⁴ with (Bu¹Me₂Si)₂Se (eq 1). The structures of the selenido complexes [η⁴-Me₈taa]-

Ti=Se²⁵ and [η⁴-Me₈taa]V=Se²⁶ have been determined by X-ray diffraction and are characterized by Ti=Se and V=Se bond lengths of 2.269(2) and 2.210(2) Å, respectively, values that are substantially shorter than their corresponding M=E single bond lengths.^{27,28} As with their tellurido counterparts, terminal selenido complexes of titanium²⁹ and vanadium^{20,23b,30–32} are rare, with only the latter having been structurally characterized by X-ray diffraction, *e.g.*, [(Me₃Si)₂N]₂[(Me₃Si)₂SiSe]V=Se [2.1754(9) Å]^{23b} and [Et₄N]₂[(η²-SCH₂CH₂S)₂V=Se] [2.196(3) Å].^{32,33}

With regard to reactivity, the titanium selenido complex behaves similarly to the tellurido derivative [η⁴-Me₈taa]Ti=Te upon treatment with O₂, N₂O, and Me₃SiCl (Scheme 1); in addition, it also reacts with elemental selenium to give the diselenido complex [η⁴-Me₈taa]Ti(η²-Se₂)³⁴ (Scheme 1).

In summary, the macrocyclic octamethylbenzotetraaza[14]-annulene dianion has proved to be an effective ligand for supporting terminal selenido and tellurido complexes of both vanadium and titanium. Furthermore, although sufficiently stable to permit isolation, the M=E bonds in these complexes are reactive, as illustrated by conversions to [η⁴-Me₈taa]Ti=O, [η⁴-Me₈taa]TiCl₂, and [η⁴-Me₈taa]Ti(η²-Se₂).
