Received December 5, 2000

Revised Manuscript Received January 30, 2001

We report calculations of the Co–C<sub>R</sub> bond dissociation energy (BDE) in six-coordinate cobalamins (models of coenzyme B<sub>12</sub>) using gradient-corrected density functional theory (DFT) with the Becke–Lee–Yang–Parr composite exchange correlation functional (B3LYP).<sup>1</sup> The B3LYP level for computations of dissociation energies is appropriate for organometallic compounds containing a 3d-metal atom, but this level is not adequate for compounds containing metal–metal bonds as has been recently shown by Bauschlicher and co-workers.<sup>2</sup>

For purposes of present work, the homolytic cleavage of the Co–C<sub>R</sub> bond in B-[Co<sup>III</sup>(corrin)]-R was defined as the energy of the process shown in Figure 1, and the BDE of Co–C<sub>R</sub> was evaluated as

$$\text{BDE} = \text{B}[\text{Co}^{\text{III}}(\text{corrin})]\text{-R}_{\text{opt}} - \text{B}[\text{Co}^{\text{II}}(\text{corrin})]_{\text{opt}} - \text{R}_{\text{opt}} + \Delta_{\text{ZPE}} \quad (1)$$

In the above equation subscript opt indicates the energy of the DFT optimized structure, while  $\Delta_{\text{ZPE}}$  stands for vibrational zero-point energy correction. The six-coordinate cobalamin models, B-[Co<sup>III</sup>(corrin)]-R, used to calculate the Co–C<sub>R</sub> BDEs (eq 1) include the actual corrin macrocycle ring as the equatorial ligand system and imidazole (Im), dimethylbenzimidazole (DBI), or water (H<sub>2</sub>O) base as the  $\alpha$ -*trans* ligand. The sidearm and peripheral substituents of the corrin ring were left out to simplify the calculations while still retaining the important structural features. The  $\beta$  axial ligand was modeled by a series of groups with different complexity ranging from methyl (Me), ethyl (Et), through 5'-deoxy-5'-adenosyl (Ado) and isopropyl (iProp) to *tert*-butyl (tBut). Our recent studies<sup>3,4</sup> on the Co–C<sub>R</sub> bond activation in models of coenzyme B<sub>12</sub> and the development<sup>5</sup> of a quantitative

**Figure 1.** Homolytic bond cleavage in B-[Co<sup>III</sup>(corrin)]-R cobalamins. The cobalamin corrin ring is abbreviated by a square.

vibrational force field capable of modeling vibrational spectra of B<sub>12</sub> lends strong confidence that this approach is suitable for the theoretical evaluation of homolytic Co–C<sub>R</sub> bond cleavage.

Although studies directed at determining relevant Co–C<sub>R</sub> BDEs have been carried out for almost two decades<sup>6</sup> and determination of the Co–C<sub>R</sub> BDEs has been subject of intense experimental research, mainly in the Halpern<sup>7a–h</sup> and Finke<sup>7i–l</sup> laboratories, no attempt has been made to determine these BDEs quantum mechanically. The present work represents the first theoretical effort to estimate these energies theoretically (Table 1). The experimentally determined values of the Co–C<sub>R</sub> BDEs range from 17 to 34 kcal/mol for model compounds, while these values are higher (26–37 kcal/mol) for cobalamins. Comparison with available experimental data shows that the calculated BDE energies underestimate the experimental values, although the experimentally observed pattern for MeCbl, AdoCbl, and iPropCbl is well-captured by the current DFT computations (Tables 1 and 2). Taking into account the complexity of these calculations and the fact that they were carried out for a single molecule in gas phase without interactions from the environment, the agreement between experiment and theory is surprisingly good.

Two striking observations may be gleaned from the results of our calculations (Table 1 and Figure 2): (i) theoretically determined Co–C<sub>R</sub> BDEs do not depend on the *trans* axial ligand, and (ii) these dissociation energies correlate linearly with the Co–C<sub>R</sub> bond length. As one can expect, the dissociation energy

<sup>a</sup> Reported Co–C<sub>R</sub> BDEs were not corrected for  $\Delta_{\text{ZPE}}$  (eq 1). The  $\Delta_{\text{ZPE}}$  correction evaluated for several points was systematic and equal to ~2 kcal/mol. This value essentially cancels out with estimated correction for basis set superposition error (BSSE).

**Table 2.** Selected Experimental Values of the Co–C<sub>R</sub> BDEs in Model Compounds and Cobalamins

lowering is mainly due to Co–C<sub>R</sub> bond weakening, and the energies diminish in the order Me > Et > Ado > iProp > tBut, consistent with changes in the Co–C<sub>R</sub> bond length. Interestingly, these calculated Co–C<sub>R</sub> BDEs fall essentially along a straight line with slope and intercept equal to  $-168.25 \text{ \AA}^{-1} \text{ kcal/mol}$  and  $355.88 \text{ kcal/mol}$ , respectively. We also tested the possibility that three separate lines (each associated with different *trans* ligand) were required to reproduce these theoretical data (Table 1). We

**Figure 2.** Theoretically determined BDEs plotted as a function of the Co–C<sub>R</sub> bond length. Line parameters: slope =  $-168.25 \text{ \AA}^{-1} \text{ kcal/mol}$ , intercept =  $355.88 \text{ kcal/mol}$ .

found that two among them (B = Im and H<sub>2</sub>O) were almost identical, while a third (B = DBI) had an identical slope with a slightly lower intercept. We attributed these small differences to numerical inaccuracy and concluded that variation of the  $\alpha$ -*trans* axial base does not influence the  $\beta$  axial ligand. This phenomenon may be readily understood in terms of a molecular orbital picture which shows that essentially four molecular orbitals allow the succinct description of the N<sub>B</sub>–Co–C<sub>R</sub> bonding.<sup>8</sup> The resulting potential energy surface (PES) possesses two noninteracting Co–N<sub>B</sub> and Co–C<sub>R</sub> energy curves which are inherently coupled to the cobalt atom of the corrin macrocycle through the cobalt d<sub>z<sup>2</sup></sub> orbital.<sup>8</sup> This topology of the PES is consistent with spectroscopic<sup>9</sup> and our recent theoretical studies<sup>3,4</sup> which show that elongation of the Co–N<sub>B</sub> bond does not influence the Co–C<sub>R</sub> bond and vice versa. Consequently, present DFT calculations support the experimental observation that the axial base is not the key controlling the Co–C<sub>R</sub> cleavage event. When the *trans* axial DBI base is replaced by water, upon protonation in acid solution [“base-off” cobalamin] the Co–C<sub>R</sub> BDE increases by 4.5 kcal/mol.<sup>7j</sup> This energy increase is comparable to experimental error (Table 2).

How can these findings be associated with the possible implications for catalytic Co–C<sub>R</sub> activation in coenzyme B<sub>12</sub>-dependent enzymes? The Co–C<sub>R</sub> dissociation enthalpy is  $33 \pm 2 \text{ kcal/mol}$  for AdoCbl and the thermal homolysis rate at 25 °C is only  $4 \times 10^{-10} \text{ s}^{-1}$ .<sup>7i</sup> In AdoCbl-dependent enzymes this rate is increased by a factor of  $10^{12 \pm 1}$ , implying a  $\sim 15 \text{ kcal/mol}$  destabilization of the Co–C<sub>R</sub> bond.<sup>7j,10</sup> According to the present work,  $\sim 15 \text{ kcal/mol}$  BDE lowering for B-[Co<sup>III</sup>(corrin)]-Ado requires  $\sim 0.1 \text{ \AA}$  elongation of the Co–C<sub>R</sub> bond. This estimate is exactly the same as one obtained on the basis of crystallographic considerations<sup>11</sup> and consistent with calculations in the presence of an external electric field required for Co–C<sub>R</sub> bond labilization.<sup>3,4</sup>
