Tetrahdraryllithium: Synthesis, Characterization, and Reactivity

Akira Sekiguchi* and Masanobu Tanaka

Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305-8571, Japan

Received August 1, 2003; E-mail: sekiguch@staff.chem.tsukuba.ac.jp

Tetrahdrane is the smallest and most strained cage compound, and its highly symmetrical structure and unusual bonding nature attract organic chemists.¹ However, many attempts to isolate the parent tetrahdrane have been unsuccessful because of the high reactivity and very short lifetime caused by the strain in this molecule.^{1,2} In 1978, Maier and co-workers succeeded in synthesizing tetrakis(*tert*-butyl)tetrahdrane (**1**),³ in which the four bulky *t*Bu-substituents kinetically stabilize the tetrahdrane skeleton from ring-opening bond cleavage, the so-called "corset effect". However, if one of the *tert*-butyl substituents in **1** is replaced with a smaller group, this effect is lost. Indeed, phenyl- and methyl-substituted tetrahdrane derivatives were not detected, even under matrix isolation conditions.⁴ Recently, we succeeded in synthesizing tetrakis(trimethylsilyl)tetrahdrane (**2**) by the photochemical isomerization of tetrakis(trimethylsilyl)cyclobutadiene.^{5,6} The "corset effect" in **2** is smaller than that in **1** because of the longer C–Si bonds. However, the four σ -donating trimethylsilyl groups of **2** electronically stabilize the highly strained tetrahdrane skeleton.^{7,8} This influence dramatically increases the thermal stability of **2** despite the enormous strain energy expected for a tetrahedral skeleton.⁵

Electropositive lithium is also an electron-donating atom and therefore was expected to stabilize tetrahdrane in a way similar to that by the Me₃Si groups in **2**.⁵ In this work, we synthesized tris(trimethylsilyl)tetrahdraryllithium (**3**) by the reaction of **2** with MeLi. Compound **3** was characterized by NMR spectroscopy and X-ray crystallography. This is the first stable example of a lithium derivative of tetrahdrane. Furthermore, we were successful in the derivatization of **3** with cyclopentadiene and dimethyl sulfate to form new, hydrogen- and methyl-substituted tetrahdranes, respectively.

Tris(trimethylsilyl)tetrahdraryllithium (**3**) was synthesized by the reaction of **2** with excess methyl lithium in THF at room temperature and was isolated as a colorless solid in 67% yield (Scheme 1).^{9,10} Compound **3** is air and moisture sensitive, but

Scheme 1

thermally stable. The ¹H and ¹³C NMR spectra of **3** in benzene-*d*₆ demonstrated its C_{3v} symmetry. Only one signal at –0.03 ppm was

observed for the trimethylsilyl groups in the ¹H NMR spectrum, and three signals appeared at –27.0 (ring C–Li), –22.0 (ring C), and 1.6 (SiMe₃) ppm in the ¹³C NMR spectrum. The large upfield shift of the ring C atom is typical for tetrahdrane.^{3,5,8} The Li-substituted skeletal carbon atom shows a remarkable upfield shift relative to that of **2** (–20.5 ppm) because of its carbanion character.

The molecular structure of **3** has been unambiguously characterized by X-ray crystallography, as shown in Figure 1. We were able to grow single crystals by changing the ligand from THF to tetramethylethylenediamine (TMEDA).¹¹ Three TMEDA molecules are coordinated to two tetrahdraryllithium molecules, and one of three TMEDA molecules bridges two tetrahdraryllithium units.

Compared with the regular tetrahedral structure of **2**, the structure of **3**•(TMEDA)_{1.5} represents a stretched tetrahedron with Li–C bond length of 2.076(2) Å. The endocyclic C(Li)–C(SiMe₃) bond lengths range from 1.5408(15) to 1.5441(15) Å (av 1.5425(15) Å), and are longer than the endocyclic C(SiMe₃)–C(SiMe₃) bond lengths, which range from 1.4961(15) to 1.5009(15) Å (av 1.4986(15) Å).

Figure 1. ORTEP drawing of **3**. Hydrogen atoms are omitted for clarity. Selected bond lengths (Å): C1–C2 = 1.4961(15), C1–C3 = 1.5009(15), C1–C4 = 1.5441(15), C2–C3 = 1.4988(15), C2–C4 = 1.5426(15), C3–C4 = 1.5408(15), C4–Li1 = 2.076(2). Selected bond angles (deg): C1–C2–C4 = 61.06(7), C1–C4–C2 = 57.98(7), C2–C1–C4 = 60.96(7), C3–C2–C4 = 60.86(7), C2–C3–C4 = 60.98(7), C2–C4–C3 = 58.17(7), C3–C1–C4 = 60.77(7), C1–C3–C4 = 61.00(7), C1–C4–C3 = 58.23(7), C2–C1–C3 = 60.01(7), C1–C2–C3 = 60.15(7), C1–C3–C2 = 59.83(7).

Tetrahdraryllithium **3** readily undergoes reaction with a variety of electrophiles, which allowed us to introduce a methyl group onto the tetrahdrane skeleton. The methyl group is the smallest alkyl group and was not expected to exert appreciable steric or electronic

influences. Reaction of **3** with an equivalent amount of dimethyl sulfate in C_6D_6 at room temperature produced methyltris(trimethylsilyl)tetrahedrane (**4**) as a colorless oil in 20% yield (Scheme 2).^{10,12} Methyl-substituted tetrahedrane **4** is less sterically protected compared with **2**; however, no decomposition of **4** was observed upon standing in air or after heating at 100 °C for 3 h.

Scheme 2

This surprising result prompted us to introduce a hydrogen substituent on tetrahedrane, since unsubstituted tetrahedrane has been among the most attractive synthetic challenges. Tris(trimethylsilyl)tetrahedrane (**5**) was prepared by the reaction of **3** with cyclopentadiene as a colorless oil in 32% yield (Scheme 2).^{10,13} In the 1H NMR spectrum, the signal of the proton attached to the tetrahedrane skeleton appeared at 2.85 ppm, being deshielded because of the high s -character of the ring C–H bond. The C–H coupling constant ($^1J_{C-H} = 255.6$ Hz) is comparable to that of acetylene ($^1J_{C-H} = 249.0$ Hz).¹⁴ From the empirical correlation ($^1J_{C-H} = 5.70s - 18.4$ Hz),¹⁵ we estimated the s -character of the ring C–H bond to be 48% ($sp^{1.08}$). Hydrogen-substituted tetrahedrane is also air- and thermally stable up to 100 °C. The stability of tetrahedrane derivatives **4** and **5** is surprising in light of previous reports.⁴ The most important stabilizing factor should be attributed to the electronic effect of the trimethylsilyl groups.

Acknowledgment. This work was supported by a Grant-in-Aid for Scientific Research (Nos. 13440185, 14044015, 14078204) from the Ministry of Education, Science and Culture of Japan, JSPS Research Fellowship for Young Scientists (M.T.), TARA (Tsukuba

Advanced Research Alliance), and COE (Center of Excellence) program. We thank Professor Günther Maier for helpful discussions and advice.

Supporting Information Available: Experimental procedures, spectral data, tables of crystallographic data including atomic positional and thermal parameters for **3** (PDF). X-ray crystallographic file in CIF format. This material is available free of charge via the Internet at <http://pubs.acs.org>.
