Siloxy alkynes represent a versatile synthetic platform for the development of new C–C bond forming reactions.^{1–3} We previously established that soft and hard electrophiles (AuCl and HNTf₂) were capable of efficient activation of siloxy alkynes toward subsequent intramolecular additions of arenes and alkenes via the intermediacy of highly reactive ketenium ions.^{3d,e} In this communication, we further expand this broadly useful reactivity concept and describe the discovery of the first Brønsted acid-promoted 5-*endo-dig* cyclizations of 1-siloxy-1,5-diyne, which proceed with concomitant formation of C–Hal bonds as a result of halide abstraction from a halocarbon by the intermediate alkenyl cation. This process is enabled by chemoselective activation of an electron-rich siloxy alkyne moiety of the diyne cyclization precursor. Excellent diastereoselectivity of the present method combined with the ability to access a range of β -halo enones compares this approach favorably to the known methods for preparation of this class of compounds.⁴

In the course of our continuing investigation aimed at the development of new C–C bond forming reactions involving electron-rich alkynes, we found that treatment of 1-siloxy-1,5-diyne **1** with HNTf₂ resulted in efficient formation of enone **2** containing the β -chloride that originated from CH₂Cl₂ (Scheme 1).⁵ Structural

Scheme 1

assignment of **2** was based on COSY, NOESY, HMBC, MS, and preparation by an independent method.⁴

Further studies demonstrated that HNTf₂ is a highly effective Brønsted acid promoter.⁶ Broad evaluation of other Brønsted acids revealed that only HBF₄ or HOTf was capable of promoting siloxy diyne cyclizations. However, the reactions proceeded with significantly lower efficiency (32 and 22% yield, respectively). These intriguing results could be explained by the increased Brønsted acidity of HNTf₂ in a polar aprotic solvent combined with a low nucleophilicity of the trifluoromethane sulfonimide anion.⁷ Interestingly, the use of either CSA or anhydrous HCl resulted in formation of alternative reaction products.⁸

The use of other halogen sources, such as CHCl₃, CH₂Br₂, or MeI, resulted in efficient incorporation of chloride, bromide, and iodide into the reaction products **2**, **3**, and **4**, respectively (Table 1, entries 1, 2, and 3). Subjection of phenyl-substituted enynes **5** and **7** to the general reaction protocol efficiently afforded the expected enones **6** and **8**, respectively (entries 4 and 5). These results indicate that aryl substitution at the 8- and 9-position of the diyne was well tolerated despite the possible intra- or intermolecular arylation of the intermediate alkenyl cation (*vide infra*). Subjection of 3,3-dimethyl diyne **9** to HNTf₂ in either CH₂Br₂ or MeI afforded

Table 1. HNTf₂-Promoted Cyclizations of 1-Siloxy-1,5-diyne

Entry	Siloxy Alkyne	Haloalkane	Product ^a	Yield, % ^b
1		CHCl ₃		60
2		CH ₂ Br ₂		71
3		MeI		74
4		CH ₂ Cl ₂		50
5		CH ₂ Cl ₂		70
6		CH ₂ Br ₂		81
7		MeI		69
8		CH ₂ Cl ₂		71

^a General reaction protocol for CH₂Cl₂: Trifluoromethanesulfonimide (0.28 mmol) was dissolved in CH₂Cl₂ (10 mL), cooled to –78 °C, and treated with siloxy diyne (0.25 mmol) dissolved in CH₂Cl₂ (5 mL). The resulting solution was stirred at –78 °C for 10 min, allowed to reach room temperature, diluted with CH₂Cl₂ (30 mL), and subjected to a standard aqueous work up. The crude product was purified by flash chromatography on silica gel. ^b Refers to isolated yields of spectroscopically pure products that were fully characterized by NMR, IR, and MS.

the expected enones **10** and **11** (entries 6 and 7), indicating that increased steric congestion at the siloxy alkyne terminus was well tolerated. Finally, TIPS-protected primary alcohol **12** was retained under our standard cyclization protocol (entry 8), illustrating

Scheme 2

functional group compatibility of the present method to the use of silyl protecting groups. While a range of 1,5-diyne efficiently participated in the cyclization process, subjection of the corresponding 1-siloxy-1,6-diyne to HNTf₂ afforded a complex product mixture under the current conditions.

Our mechanistic analysis is presented in Scheme 2. The reaction begins by protonation of the more electron-rich siloxy alkyne terminus of diyne **A**. Attack of the other alkyne moiety onto the resulting ketenium ion **B** leads to the 5-endo-dig cyclization, furnishing alkenyl cation **C**.⁹ Subsequent reaction of alkenyl cation with the halocarbon results in the cleavage of the R–X bond,¹⁰ presumably via the intermediacy of halonium ion **D**.^{5c} We believe that low nucleophilicity of NTf₂[–] is uniquely responsible for efficient generation and interception of highly reactive cationic intermediates **B** and **C**. Subsequent protodesilylation of silyl dienol ether **E** affords the observed halo enone **F**. While protodesilylation of **E** proceeds competitively with the initial protonation of siloxy alkyne **A**, silyl dienol ether **E** can be detected or isolated as an exclusive reaction product by conducting the reaction with 20–30 mol % of HNTf₂, or by subjecting a diyne to 110 mol % of HNTf₂, followed by treatment with Et₃N.¹¹

Interestingly, subjection of diyne **1** to HNTf₂ in benzene afforded tetrasubstituted enone **14** (eq 1) as a single alkene isomer (dr > 97:3). The outcome of this experiment can be rationalized by the interception of alkenyl cation **C** by benzene, demonstrating that this newly developed concept can be applied to a range of nucleophiles.

In closing, we have developed the first HNTf₂-promoted 5-endo-dig cyclizations of 1-siloxy-1,5-diyne featuring chemoselective activation of the electron-rich siloxy alkyne moiety and an unusual halide abstraction by the intermediate alkenyl cation. In addition to enabling rapid and diastereoselective assembly of a range of substituted β-halo enones, this process provides another demonstra-

tion of efficient generation of highly reactive ketenium ions that are poised for interception by the proximate alkyne to provide a simple concept for generating new C–C and C–Hal bonds.

Acknowledgment. This work was supported by the NSF CAREER (CHE-0447751). We thank Liming Zhang for the initial studies on cyclizations of siloxy diynes. S.A.K. thanks the Dreyfus Foundation for a Teacher-Scholar Award, Amgen for a New Investigator's Award, and GlaxoSmithKline for a Chemistry Scholars Award. S.A.K. is a fellow of the Alfred P. Sloan Foundation.
