Vicinal diamines are very important functional moieties which are present in various biologically active compounds and have also been widely used as chiral control elements in asymmetric synthesis.¹ Diamination of olefins presents an attractive strategy for the synthesis of vicinal diamines. Various metal-free¹.² or metal-mediated¹.³,⁴ processes have been developed. Metal-catalyzed diaminations have also been reported.⁵,⁶ Very recently, it has been shown that both intermolecular diamination of conjugated dienes⁶a and intramolecular⁶b diamination of terminal olefins with ureas can be achieved using Pd(II) as catalyst. For the intermolecular process, the diamination occurred regioselectively at less-substituted double bonds of dienes. In these cases, the amination is likely to proceed via a Pd(II)-promoted aza-Wacker-type process (trans-amino-palladation),³g,6,7 followed by the replacement of the C−Pd bond with a C−N bond.³g,6,7

As part of our general interest in synthetic transformations of dioxirane⁸ and its nitrogen analogues, we have been exploring a possible metal-catalyzed diamination of olefins via an oxidative addition to the N-N bond of diaziridine 1 to form diamido species 2, followed by a migratory insertion to a double bond to form 3° and a subsequent reductive elimination to form 4 (Scheme 1). Herein we wish to report our preliminary efforts on this subject.

The diamination was examined with olefins and di-t-butyldiaziridinone (6)10,11 using Pd(PPh3)4 as catalyst. Among the olefins tested, conjugated dienes were found to be very effective substrates (Scheme 2). For example, subjecting trans-1,3-pentadiene (5a) to the reaction conditions (Scheme 2) for 30 min led to a clean diamination product (7a) in 94% yield (Table 1, entry 1). The reaction occurred highly regioselectively at the internal double bond and highly stereoselectively as well. 12 As shown in Table 1, this diamination can be extended to a variety of dienes including both electron-rich (Table 1, entries 8 and 9) and electron-deficient dienes (Table 1, entry 10). Trisubstituted double bonds can also be diaminated (Table 1, entries 11-13). When a conjugated triene was used, the diamination occurred cleanly at the middle double bond (Table 1, entries 14–15). In all these cases (Table 1, entries 1–15), essentially only one regio- and stereoisomer was obtained.12 It appears that only trans- and trisubstituted double bonds react under the reaction conditions. For example, no diamination was observed when cis-1,3-pentadiene was used. Therefore, when a mixture of E and Z dienes were used (Table 1, entries 2, 7, and 11), only the *E* isomer reacted and the *Z* isomer was enriched after the reaction. The diamination also occurred for the dienes containing geminal disubstituted double bonds (Table 1, entries 16 and 17). In these two cases, the reaction occurred also regioselectively and stereoselectively.¹³ The stereochemistry of the diamination products (7) was tentatively assigned by comparing the NOE of compounds 7b, g, h, and p (Table 1, entries 2, 7, 8, and 16) with 7q (Table 1, entry 17) (see Supporting Information). The X-ray structure of compound 7n (Table 1, entry 14) further supports the assigned stereochemistry (Scheme 3).

 $[^]a$ All reactions were carried out with di-t-butyldiaziridinone (6) (0.2 mmol), diene or triene (0.24 mmol), 1.2 equiv), and Pd(PPh₃)₄ (0.02 mmol) in benzene- d_6 (0.6 mL) in an NMR tube at 65 °C under argon unless otherwise stated. b A mixture of E and Z isomers was used. For entry 2, diene (0.53 mmol, E/Z = 1/1.2, E isomer: 0.24 mmol); for entry 7, diene (0.48 mmol, E/Z = 1/1, E isomer: 0.24 mmol); for entry 11, diene (0.34 mmol, E/Z = 2.5/1, E isomer: 0.24 mmol). c Containing <10% Z isomer. d Compounds are acid sensitive and were purified on less acidic silica gel (latrobeads 6RS-8060, Mitsubishi Kagaku Iatron, Inc. Japan). c Isolated yield based on 6.

The deprotection of compound **7b** (Table 1, entry 2) was investigated. Treating **7b** with CF₃CO₂H (TFA) at 75–80 °C for 2

Scheme 1

Scheme 2

Scheme 3. The X-ray Structures of Compounds 7n and 9a

Scheme 4

Scheme 5. A Proposed Catalytic Cycle for Diamination

h gave a clean deprotection product **8** in 98% yield (Scheme 4). Interestingly, monodeprotection was also possible when the reaction was carried out at room temperature, giving **9a** as major product (Scheme 4). The structure of **9a** was determined by X-ray (Scheme 3). The selective monodeprotection provides opportunities to introduce different groups on the two nitrogens if it is desired.

While a precise reaction mechanism awaits further study, a plausible catalytic cycle is shown in Scheme 5. The Pd(0) first inserts into the N-N bond of diaziridinone 6 to form a four-membered Pd(II) species (10). Upon complexing with diene 5 and a migratory insertion, compound 10 is then converted into π -allyl Pd complex 12, which then undergoes a reductive elimination to form product 7 and regenerate the Pd(0) catalyst.

In summary, a diamination for a variety of conjugated dienes and trienes has been effectively achieved using di-t-butyldiaziri-dinone as the nitrogen source and Pd(PPh₃)₄ as catalyst, giving the

diamination products in good yields with high regio- and stereo-selectivities. This Pd(0)-catalyzed diamination is mechanistically distinct from the Pd(II)-catalyzed process, thus resulting in different regioselectivity.⁶ Further studies of the reaction mechanism, development of a more effective catalytic process with different nitrogen sources and metal catalysts, and expansion of the substrate scope as well as the asymmetric process are currently underway.

Acknowledgment. We are grateful to the generous financial support from the Monfort Foundation (CSU).
