

Use of Alizarin Red S for Determining Critical Micelle Concentration of Cationic Surfactants

WAHID U. MALIK and SURENDRA PAL VERMA,
Chemical Laboratories, University of Roorkee, Roorkee, India

Abstract

The critical micelle concentrations of cetyl trimethyl ammonium bromide and cetyl pyridinium bromide have been calculated by a spectral-dye method. Alizarin red S at pH 9.12 was found to be suitable for these two cationics. Two shifts in the dye maximum, one due to complex formation ($500\text{ m}\mu$ or $525\text{ m}\mu$) and the other due to the dye-surfactant complex solubilized in the micelles of the cationics were realized. The critical micelle concentration was represented by the point of intersection of two curves at wavelength $500\text{ m}\mu$ and $550\text{ m}\mu$ for cetyl pyridinium bromide and $525\text{ m}\mu$ and $550\text{ m}\mu$ for cetyl trimethyl ammonium bromide.

Introduction

IT HAS BEEN KNOWN for more than thirty years that indicator dyes have their colors altered when present in solution along with surfactants (1,2). Fajans (3) investigated the effect of dye adsorption on ionic surfaces. Deutsch (4) described striking examples of effects on indicators when adsorbed at oil-water interfaces. In 1934, Hartley (5) studied the effects of anionic, cationic and nonionic detergents on a large number of dyes. The work of Sheppard and Geddes (6) on the spectrum of pinacyanol and cationic detergents was further extended by Corrin et al. (7), whose investigations led them to develop a method

FIG. 1. Absorption spectra of $6.7 \times 10^{-5}\text{M}$ alizarin red S for different concentrations of CPB.

Curve 1— $6.7 \times 10^{-5}\text{M}$ dye + $3.3 \times 10^{-4}\text{M}$ CPB
Curve 2— $6.7 \times 10^{-5}\text{M}$ dye + $6.6 \times 10^{-4}\text{M}$ CPB
Curve 3— $6.7 \times 10^{-5}\text{M}$ dye + $10.0 \times 10^{-4}\text{M}$ CPB
Curve 4— $6.7 \times 10^{-5}\text{M}$ dye + $13.3 \times 10^{-4}\text{M}$ CPB
Curve 5— $6.7 \times 10^{-5}\text{M}$ dye + $33.3 \times 10^{-4}\text{M}$ CPB
Curve 6— $6.7 \times 10^{-5}\text{M}$ dye + $53.3 \times 10^{-4}\text{M}$ CPB
Curve 7— $6.7 \times 10^{-5}\text{M}$ dye + $80.0 \times 10^{-4}\text{M}$ CPB

(8) for determining the critical micelle concentration (cmc). Hiskey and Downey (9), Mysels and Mukerjee (10), Herzfeld (11), Ginn and Harris (12), etc., also used this technique to determine the cmc of some cationic and anionic surfactants.

The apparent simplicity of the above methods of providing color changes has been used to determine the cmc values of cetyl trimethyl ammonium bromide and cetyl pyridinium bromide by employing alizarin red S. This dye is more sensitive than the other dyes so far employed in the study of cationic surfactants.

Experimental

Reagents

Cetyl trimethyl ammonium bromide (CTMAB) and cetyl pyridinium bromide (CPB) were obtained from British Drug House and were recrystallized from acetone. The stock solutions were prepared in doubly distilled water (all glass). Alizarin red S used in this study was also a BDH product and was used without further purification. The buffers, Walpole, Mellavine and borax, were prepared in the laboratory.

Apparatus

A Bausch and Lomb Spectronic 20 was used for the absorption measurements and the pH of the solutions were measured by a Cambridge Bench Type pH meter.

Samples

Following sets of solutions were prepared from 10^{-3}M dye stock solutions: (a) 15 ml buffers containing 0.1 to 1.0 ml of dye solutions; (b) 1 ml dye in 15 ml buffer containing 1 to 12 ml of cationic surfactant solutions. Buffers of pH 2.00, 7.00 and 9.12 were used in both sets.

Results and Discussion

The spectrum of alizarin red S solution changes very markedly with increasing concentration of cationic surfactants. At pH 9.12 the shift in the maximum of the dye in presence of cationic surfactant is very large ($445\text{ m}\mu$ to $550\text{ m}\mu$) in comparison to those observed at the other two pH values. At pH 7.00 in the initial concentrations of the surfactant, precipitation occurs which might be attributed to a dye-surfactant complex. However, on further addition of surfactant the precipitate redissolves and the dye gives the same maximum as in the alkaline range, the shift being from $515\text{ m}\mu$ to $550\text{ m}\mu$. At pH 2.00 no appreciable shift in dye maximum could be observed ($415\text{ m}\mu$ to $425\text{ m}\mu$). Figure 1 represents some typical data to illustrate the effect observed with gradual addition of cetyl pyridinium bromide.

We have shown in another communication (13) that in dilute surfactant solutions the binding ratio between the surfactant and the dye molecule is 1:1. This ratio, however, changes with the increase in the surfactant concentration due to the appearance of micelles in the solution. At pH 9.12 two maximum

TABLE I
Influence of CTMAB on the Absorption Maximum of Alizarine Red S

Conc. of surfactant $\times 10^{-5}M$	Absorption maximum at different pH values		
	(2.00)	(7.00)	(9.12)
0.00	415 $m\mu$	515 $m\mu$	445 $m\mu$
3.3	415 $m\mu$	515 $m\mu$	525 $m\mu$
6.6	415 $m\mu$	525,540 $m\mu$ (ill-defined)
10.0	415,425 (ill-defined)	525,540 $m\mu$ (ill-defined)
13.3	425 $m\mu$	550 $m\mu$
33.3	425 $m\mu$	550 $m\mu$	550 $m\mu$
53.3	425 $m\mu$	550 $m\mu$	550 $m\mu$
80.0	425 $m\mu$	550 $m\mu$	550 $m\mu$

Influence of CPB on the absorption maximum of alizarine red S

Conc. of surfactant $\times 10^{-4}M$	Absorption maximum at different pH values		
	(2.00)	(7.00)	(9.12)
0.00	415 $m\mu$	515 $m\mu$	445 $m\mu$
3.3	415 $m\mu$	515 $m\mu$	445 $m\mu$
6.6	415 $m\mu$	445 $m\mu$
10.0	415 $m\mu$	500 $m\mu$
13.3	415 $m\mu$	500 $m\mu$
33.3	425 $m\mu$	500 $m\mu$
53.3	425 $m\mu$	550 $m\mu$	550 $m\mu$
80.0	425 $m\mu$	550 $m\mu$	550 $m\mu$

shifts are observed, viz., from 445 $m\mu$ to 525 $m\mu$ and 525 $m\mu$ to 550 $m\mu$ in presence of cetyl trimethyl ammonium bromide. The first shift takes place with surfactant concentration $6.66 \times 10^{-5}M$ while the second one is observed by increasing a little beyond this concentration. In the case of cetyl pyridinium bromide the shift in the maximum is from 445 $m\mu$ to 500 $m\mu$ for the concentration $13.3 \times 10^{-4}M$ and the second maximum, i.e., 550 $m\mu$ is observed after this concentration (Table I). The maximum at 550 $m\mu$ remains unaffected by further addition of the surfactant.

We believe that the first change in maximum is due to the compound formation between the surfactant and the dye and that the next change in maximum occurs because the dye-surfactant complex is solubilized in the micelles of the surfactant. This complex is soluble at pH 9.12 but insoluble at pH

FIG. 2. Concentration (CPB) vs. optical density (dye-surfactant mixture) pH 9.12.

TABLE II
Comparative cmc Values of Cetyl Trimethyl Ammonium Bromide and Cetyl Pyridinium Bromide from Different Methods

Method	Critical micelle concentration	
	CTMAB $\times 10^{-5}M$	CPB $\times 10^{-4}M$
Spectrophotometric	26.0	42.0
Conductometric	25.0	53.0
Emf measurements method	23.8	38.0

7.00, with the result that the maximum 525 $m\mu$ (or 500 $m\mu$) at pH 9.12 is not observed here. Further addition of the surfactant results in its dissolution with the formation of micelles giving a maximum at 550 $m\mu$.

The color of the alizarine red S changes from red to violet on addition of surfactant and this change is spectrophotometrically characterized.

The Transition Region

Figure 2 shows typical changes in absorbance in the dye-surfactant mixtures. The optical densities of the dye-surfactant mixtures are plotted vs. surfactant concentration at 445 $m\mu$, 500 $m\mu$ and 550 $m\mu$ for cetyl pyridinium bromide and at 445 $m\mu$, 525 $m\mu$ and 550 $m\mu$ for cetyl trimethyl ammonium bromide. Curve A decreases at an accelerated rate. Curve B of the violet solution increases simultaneously and flattens out at higher concentrations of the surfactant. Curve C is similar to B but does not flatten until far beyond the point corresponding to micelle formation. The intersection of B and C is taken as the cmc point. This provides a proof of the fact that micelles are formed in the color transition region.

The values of cmc are given in Table II.

The value for CPB is comparable to those reported in the literature but the cmc value of CTMAB is considerably lower than that reported by others. Confirmatory evidence on CTMAB has been obtained with conductometric and emf measurements (14). The spectrophotometric method is not precise and gives the range of values rather than the true cmc value, but its simplicity compensates this limitation.
