

**95. Dipole Moment and Molecular Structure. Part XVI.  
Configuration of Ethylenic Compounds.**

By ERNST BERGMANN.

THE application of dipole moments to the determination of configuration is particularly useful in the case of rigid molecules, *e.g.*, benzene and ethylene derivatives; for the latter, only scanty data are available (Errera, *Physikal. Z.*, 1926, **27**, 764; 1928, **29**, 689; *J. Phys. Radium*, 1925, **6**, 390; Bergmann, Engel, and Meyer, *Ber.*, 1932, **65**, 446).

I. Ethylene compounds in this series contain substituents with axes of symmetry in the direction of their bonding. The following table records the dipole moments (Debye units) determined in solution.

Compound.	$\mu.$	Compound.	$\mu.$
isoStilbene .....	0 <sup>1</sup>	$\alpha\beta$ -Diphenyl- <i>p</i> -chlorostyryl bromide, m. p.	2.61

<sup>1</sup> Wildschut, Thesis, Delft, 1932.   <sup>2</sup> Smyth and Dornte, *J. Amer. Chem. Soc.*, 1931, **53**, 1296.

<sup>3</sup> For the higher-melting isomeride, which is obviously the *trans*-form, and for  $\alpha\beta$ -di-iodostilbene, no suitable solvent has been found.

For the compounds containing two halogeno- or nitro-substituents, it is evident that a vanishing moment indicates a *trans*-, and a finite moment a *cis*-configuration. The lower-melting form of  $\alpha\beta$ -diphenyl-*p*-chlorostyryl bromide would appear to be a mixture or molecular compound of the *cis*- and the *trans*-isomeride. The same explanation applies to the  $\beta$ -phenyl-*p*-chloro- and -*p*-bromo-styryl bromides (Bergmann, Engel, and Meyer, *loc. cit.*). The tendency of substances of this group to form molecular compounds is shown by the fact that tolan gives a *molecular compound* (1 : 2) with *cis*- $\alpha\beta$ -dibromo- or -dichlorostilbene, and a *compound* (1 : 1) with *trans*- $\alpha\beta$ -dibromostilbene (thermal analysis). No conclusion can be drawn as to the structure of the  $\alpha$ -bromostilbenes from the dipole moments.

II. Dipole moments are not so readily applicable for the determination of configuration of "irregular" substituents, but in favourable cases it is possible to reach definite conclusions. Ethyl cinnamate and *allocinnamate* have nearly the same moment, which is

Compound.	$\mu.$	Compound.	$\mu.$
Ethyl cinnamate.....	1.84	Methyl $\beta$ -bromocinnamate (m. p. 134°) *	1.81
Ethyl <i>allocinnamate</i> .....	1.77	(Methyl $p$ -bromobenzoate .....	1.82)

Ethyl $\alpha\beta$ -dibromocinnamate (m. p. 134°)*	1.98	$\alpha$ -Bromobenzylideneacetophenone .....	3.87
Methyl $\alpha\beta$ -dibromocinnamate (m. p. 100°)*	2.68	Ethyl $\alpha$ -bromocinnamate (m. p. 131°)* ...	2.25
Ethyl $\beta$ -bromocinnamate (m. p. 159°)* ...	2.63	Ethyl $\alpha$ -bromocinnamate (m. p. 126°)* ...	2.80

\* The m. p.'s are those of the corresponding acids.

not markedly affected by the introduction of phenyl groups into the  $\alpha$ - or the  $\beta$ -position, and similarly for benzonitrile and its *o*-phenyl compound. Ethyl  $p$ -nitrocinnamate is undoubtedly the *trans*-compound, since its moment is smaller than that of the nitro-group and similar to that of ethyl  $p$ -nitrobenzoate. The same applies to ethyl  $p$ -nitro- $\alpha$ -phenylcinnamate.

The ester of that  $\alpha\beta$ -dibromocinnamic acid in which the two bromine moments neutralise each other is expected to have the same moment as ethyl cinnamate; therefore, the acid, m. p. 100°, has formula (I), in agreement with the fact that the acid is easily cyclised to 2 : 3-dibromoindone (Pfeiffer and co-workers, *Annalen*, 1928, **467**, 158; *J. pr. Chem.*, 1929, **121**, 85) (see also Stoermer and Heymann, *Ber.*, 1913, **46**, 1253; Stoermer and Kirchner, *Ber.*, 1920, **53**, 1290; Agyar, *Nature*, 1934, **184**, 535). Also, Werner's rule ("Textbook of Stereochemistry," p. 214; Arends, *Ber.*, 1931, **64**, 1936) that *trans*- have a weaker absorption than the *cis*-isomerides is valid in the case of the  $\alpha\beta$ -dibromocinnamic acids but not in that of  $\alpha\beta$ -dichloro- and  $\alpha\beta$ -dibromo-stilbenes.

The ester of the acid (II) would be expected to have a moment similar to that of ethyl  $p$ -bromobenzoate, that of the *cis*-form being higher; therefore, the acid, m. p. 134°, corresponds to (II). These conclusions are contrary to the generally accepted views (see, e.g., Auwers and Wolter, *Annalen*, 1932, **492**, 283) and will be discussed elsewhere.

Similar considerations apply to the derivatives of benzylideneacetophenone, the moment

of which is indistinguishable from that of benzophenone (compare ethyl benzoate and ethyl cinnamate). Comparison of benzylidene-*p*-bromo- with *pp'*-dibromobenzylidene-acetophenone (2.93 and 2.03) and of benzylidene- with *p*-bromobenzylidene-acetophenone (2.92 and 2.47) shows that the latter compounds contain the polar groups in the *trans*-position. In  $\alpha\beta$ -dibromobenzylideneacetophenone the bromine moments neutralise each

other and are therefore in the *trans*-position (III). For similar reasons, in (IV) the polar groups must lie on the same side of the double bond.

Probably that form of  $\alpha$ -bromobenzylideneacetophenone investigated corresponds configuratively to the  $\alpha$ -bromocinnamic acid of m. p. 126° (moment of the ester 2.80); both have much higher moments than the non-brominated parent substances.

III. In connexion with the above investigations, the dipole moments of some related substances have been measured. The moments of ethyl *p*-nitro- and methyl *p*-bromo- $\beta$ -

<sup>1</sup> Cf. Weissberger and Sängewald (*Z. physikal. Chem.*, 1933, *B*, 20, 145) and the erroneous determination by Smyth and Dornte (*J. Amer. Chem. Soc.*, 1931, 53, 1296). <sup>2</sup> Cf. the high value found by Otto (*ibid.*, 1934, 57, 1263) and the data for phenylacetylene (Smyth and Dornte, *loc. cit.*; Bergmann and Tschudnovsky, *Z. physikal. Chem.*, 1932, *B*, 17, 116). <sup>3</sup> Cf. Pflaum and Wenzke, *J. Amer. Chem. Soc.*, 1934, 56, 1106. <sup>4</sup> Cf. Weissberger, *Z. physikal. Chem.*, 1933, *B*, 20, 145.

phenylpropionate point definitely to a kind of *cis*-structure for these compounds, since their moments are higher than those of ethyl *p*-nitro- and ethyl  $\beta$ -bromo-cinnamate, respectively. Ramart-Lucas (Solvay lecture, 1931) assigned a " *cis*-structure " to  $\beta$ -phenylpropionic acid. The moment of ethyl *p*-nitrophenylpropiolate, which is almost identical with that of ethyl *trans*-*p*-nitrocinnamate, shows that the acetylene compound is straight.

### EXPERIMENTAL.

*Materials.*—isoStilbene (Schlenk and Bergmann, *Annalen*, 1928, 463, 115) had b. p. 148—149°/17 mm. *pp'*-Dinitrostilbene (Walden and Kernbaum, *Ber.*, 1890, 23, 1959) was recrystallised from glacial acetic acid, m. p. 280—285°.  $\alpha\beta$ -Diphenylstyryl chloride (Bergmann and Bondi, *Ber.*, 1931, 64, 1467), m. p. 117°. *o*-Phenylbenzonitrile (Schlenk and Bergmann, *Annalen*, 1928, 464, 34) had m. p. 41° (Pfeiffer *et al.*, *ibid.*, 467, 174 describe it as an oil). Ethyl  $\beta$ -phenylcinnamate (Schlenk and Bergmann, *ibid.*, 1928, 463, 237), b. p. 205°/16 mm. Ethyl *p*-nitrocinnamate (Drewsen, *ibid.*, 1882, 212, 150), m. p. 141°, from alcohol. Methyl  $\alpha$ -phenylcinnamate (Bergmann and Schreiber, *Ber.*, 1933, 66, 44), m. p. 75°. Benzylideneacetophenone (Schlenk and Bergmann, *Annalen*, 1928, 463, 234), m. p. 55°. *p*-Bromobenzylideneacetophenone (Weygand, *ibid.*, 1927, 459, 118), from methyl alcohol, m. p. 120°; yield 65%. Benzylidene-*p*-bromoacetophenone (Bergmann and Hampson, *J.*, 1935, 989), from light petroleum, m. p. 105°. *pp'*-Dibromobenzylideneacetophenone (Bergmann, Hoffmann, and Meyer, *J. pr. Chem.*, 1932, 135, 252; cf. Blatt, *J. Amer. Chem. Soc.*, 1931, 53, 1139), from toluene, m. p. 185—186°. Tolan (Schlenk and Bergmann, *Annalen*, 1928, 463, 76), b. p. 158°/12 mm., from light petroleum, m. p. 60°. Ethyl phenylpropiolate, from the acid (Schlenk and Bergmann, *ibid.*, p. 82), had b. p. 137—138°/12 mm. Ethyl *p*-nitrophenylpropiolate, from the crude acid (Perkin and Bellenot, *J.*, 1886, 49, 441), had m. p. 126°. Phenylchloroacetylene (Truchat, *Ann. Chim.*, 1931, 16, 309), b. p. 74°/15 mm.  $\omega$ -Nitrostyrene (Thiele and Haeckel, *Annalen*, 1902, 325, 7), from methyl alcohol, m. p. 60°.  $\omega$ -Ethoxystyrene (Nef, *Annalen*, 1899, 308, 26), b. p. 98—100°/13 mm.  $\omega$ -Chlorostyrene (Erlenmeyer, *Ber.*, 1881, 14, 1868; see Blitz, *Annalen*, 1879, 296, 266), b. p. 89°/17 mm. Ethyl cinnamate (b. p. 263°), methyl *p*-bromobenzoate (m. p. 81°), ethyl *p*-nitrobenzoate (m. p. 57°), ethyl  $\beta$ -phenylpropionate (b. p. 242°), and  $\omega$ -bromostyrene (b. p. 108°/20 mm.) were commercial samples.

$\alpha\beta$ -*Dichlorostilbenes.* (a) By Blank's method (*Annalen*, 1888, **248**, 21), 30 g. of tolan on chlorination by 12 g. of the gas afforded first 0·8 g. (Found : C, 67·2; H, 4·3. Calc. for  $C_{14}H_{10}Cl_2$  : C, 67·5; H, 4·0%), m. p. 143—144°; and ether extraction of the residue of the mother-liquors gave a product which, after several recrystallisations from methyl alcohol, had m. p. 67—69°, and was a *molecular compound* (see below) (Found : Cl, 20·9.  $2C_{14}H_{10}Cl_2, C_{14}H_{10}$  requires Cl, 21·0%).

(b) Tolan tetrachloride (24 g.; Redsko, *Ber.*, 1889, **22**, ref., 760) was heated with copper bronze (25 g.) (see Onufrowicz, *Ber.*, 1884, **17**, 835) under reduced pressure (20 mm.) in a Claisen flask. At 220° (bath temp.) a colourless liquid distilled over, which crystallised rapidly. The crude product was shaken for 12 hours with 100 c.c. of alcohol (which does not dissolve the higher-melting  $\alpha\beta$ -dichlorostilbene formed), the alcohol distilled off, and the residue triturated with ice-cold light petroleum. The substance, recrystallised from methyl alcohol, had m. p. 60°. When methyl-alcoholic solutions of this (2 mols.) and tolan (1 mol.) were mixed, characteristic crystals of the above double compound were obtained; m. p. and mixed m. p. 65—66°.

$\alpha\beta$ -*Dibromostilbenes.* (a) The bromination product of tolan in ether (Limprecht and Schwanert, *Ber.*, 1871, **4**, 379) was extracted with hot alcohol after evaporation of the ether. The greater part of the higher-melting isomeride remained undissolved, and was recrystallised from propyl alcohol; m. p. 206—208°; yield, 70% (Found : C, 49·8; H, 3·2. Calc. for  $C_{14}H_{10}Br_2$  : C, 49·7; H, 3·0%). The alcoholic extract gave on cooling a further crop of the higher-melting compound; its mother-liquor gave on evaporation a residue, which was recrystallised several times from methyl alcohol. The long brittle needles, m. p. 77°, were a *molecular compound* (see below) (Found : C, 59·3; H, 3·7.  $2C_{14}H_{10}Br_2, C_{14}H_{10}$  requires C, 59·0; H, 3·5%).

(b) 5 G. of the higher-melting compound were partly isomerised (see Limprecht and Schwanert, *loc. cit.*) by 18 hours' heating with 20 c.c. of water in a sealed tube at 180°. From the crystalline mass obtained, the lower-melting isomeride was extracted with cold alcohol; the solution was evaporated, and the residue triturated with ice-cold light petroleum, filtered off, and several times fractionated from the same solvent; m. p. 66—68° (yield, very small). With tolan in light petroleum (ratio 2 : 1), the substance gave the above double compound, m. p. 77°.

$\alpha\beta$ -*Di-iodostilbene.* The product from tolan and iodine (Fischer, *Annalen*, 1882, **211**, 233) was triturated with cold chloroform, and the residue several times recrystallised from the same solvent; leaflets, m. p. 204° (decomp.) (yield, 10%) (Found : I, 58·6. Calc. for  $C_{14}H_{10}I_2$  : I, 59·0%).

$\alpha\beta$ -*Dinitrostilbene.* The crystals prepared by Schmidt's method (*Ber.*, 1901, **34**, 621) were recrystallised six times from alcohol; yellowish prisms, m. p. 185—186°. The lower-melting isomeride could not be detected.

$\alpha\beta$ -*Diphenyl-p-chlorostyryl bromides.* Koelsch (*J. Amer. Chem. Soc.*, 1932, **54**, 2487) stated that apparently uniform preparations of certain triarylvinyl bromides gave, on treatment with magnesium and then with carbon dioxide, mixtures of stereoisomeric triarylacrylic acids. It is more likely that the ability of bromides to form mixed crystals or molecular compounds prevents final purification in these cases.  $\alpha\beta$ -Diphenyl-*p*-chlorostyrene (31 g.) in glacial acetic acid (100 c.c.) was treated with bromine (5·2 c.c.) in the same solvent (10 c.c.), and the resulting crystals were heated with benzene. Hydrogen bromide was vigorously evolved, and the clear solution obtained was evaporated, the residue washed with methyl alcohol, and recrystallised several times from propyl and amyl alcohol; yield, 14·5 g., m. p. 160°. The glacial acetic acid mother-liquor was poured into a large volume of water, extracted with ether, and the solution evaporated. Several recrystallisations of the remaining crop from alcohol and glacial acetic acid gave a substance, m. p. 112—113° (not sharp), which was proved by dipole-moment measurements to be a double compound of both the possible isomerides.

$\alpha$ -*Bromostilbenes.* (a) From stilbene dibromide (m. p. 239°), by the method of Wislicenus and Seeler (*Ber.*, 1895, **28**, 2693), an oil was finally obtained, but it could not be purified because distillation (b. p. 187—191°/17 mm.) caused partial isomerisation.

(b) The same procedure with stilbene dibromide (m. p. 110°; 7·5 g.) and potassium hydroxide (1·3 g.) gave the solid  $\alpha$ -bromostilbene, which could be separated from the crude product by means of cold benzene. The benzene solution was evaporated in a vacuum desiccator, and the remaining crystals had m. p. 31°.

*Ethyl allocinnamate.* Ethyl phenylpropionate (15 g.) in alcohol (20 c.c.) was catalytically hydrogenated in presence of a palladium-barium sulphate catalyst (1·5 g.) at room temperature. The required amount of hydrogen was absorbed in about 3 hours; b. p. 131—134°/17 mm.; yield 11 g. (Found : C, 75·0; H, 7·0. Calc. for  $C_{11}H_{12}O_2$  : C, 75·0; H, 6·8%).

*Methyl p-nitro- $\alpha$ -phenylcinnamate.* Prepared by recorded methods (Bakunin, *Gazzetta*, 1895,

25, I, 146, 175; 1901, 31, II, 83; see Sudborough and Lloyd, J., 1898, 73, 90), this formed prisms, m. p. 141—142°, from alcohol.

$\alpha\beta$ -Dibromocinnamic acids. Phenylpropionic acid (40 g.) was treated with bromine (44 g.) in ice-cold chloroform, the solvent evaporated, and the residue triturated with benzene and light petroleum (1 : 1) and recrystallised from benzene. The large colourless leaflets of the *trans*-isomeride (20 g., m. p. 134°) crystallised first, then the yellow prisms of the *cis*-acid (1·2 g., m. p. 98°). The addition of bromine is, therefore, largely a " *trans*-reaction." The methyl ester of the *cis*-acid (1·2 g.) was prepared by use of diazomethane (0·2 g.) in ether; yield, 1 g., b. p. 171—172°/18 mm. (Found : C, 37·7; H, 2·7. Calc. for  $C_{10}H_8O_2Br_2$  : C, 37·5; H, 2·5%). In the same way the *trans*-acid (5 g.) and diazomethane (1 g.) gave the corresponding methyl ester (4·1 g.), b. p. 167°/15 mm. On esterification with 3% alcoholic hydrochloric acid (boiling for 48 hours), no stereochemical rearrangement of the *trans*-acid occurred; the ester, b. p. 174°/12 mm., contained the bromine atoms in the *trans*-position.

$\beta$ -Bromocinnamic acids. By the method of Sudborough and Thompson (J., 1903, 83, 1156), phenylpropionic acid (22 g.) afforded ultimately 20 g. of the *trans*-acid (m. p. 132—134°) and 10·5 g. of the *cis*-acid (m. p. 159°), the preponderance of the former acid being contrary to recorded results. (Debromination of the  $\beta$ -bromocinnamic acids is accompanied by total configurational inversion, and is therefore not simply a substitution of hydrogen for the bromine atom, but more probably addition of hydrogen to the double bond, followed by elimination of hydrogen bromide; in the intermediate stage, the configurational rigidity of the molecules is lost and steric change can occur.) The higher-melting acid (5 g.) gave with diazomethane (1 g.) in ether the methyl ester (3·9 g.), m. p. 58°, from alcohol. The lower-melting acid was quantitatively esterified with 3% alcoholic hydrochloric acid; the ester had b. p. 171—172°/18 mm. (Found : C, 51·8; H, 4·5.  $C_{11}H_{11}O_2Br$  requires C, 51·8; H, 4·3%). In both esterification reactions, no configurational change occurs (cf. Auwers and Schmellenkamp, Ber., 1921, 54, 624; James, J., 1911, 99, 1626).

$\alpha\beta$ -Dibromobenzylideneacetophenone. This was prepared according to Dufraisse (*Compt. rend.*, 1920, 171, 1062) from benzoylphenylacetylene (Nef, *Annalen*, 1899, 308, 267), and recrystallised from alcohol, and then from light petroleum; m. p. 113—114°.  $\beta$ -Bromobenzylideneacetophenone (Dufraisse, *loc. cit.*) was a yellow, thick oil, b. p. 219—220°/14 mm.; and the  $\alpha$ -isomeride (Abell, J., 1912, 101, 1002) had b. p. 218—219°/14 mm., but could not be induced to crystallise.

$\alpha$ -Bromocinnamic acids. (a) Higher-melting acid. Phenylpropionic acid was treated with a stream of gaseous hydrogen bromide (see J., 1903, 83, 1156), and the product purified through the barium salt; m. p. 130—131°. Esterification with 3% alcoholic hydrogen chloride (4 hours' boiling) afforded the ester, b. p. 169°/15 mm., in 75% yield.

(b) Lower-melting acid.  $\alpha\beta$ -Dibromo- $\beta$ -phenylpropionic acid was treated with alcoholic potash solution (Sudborough and Thompson, *loc. cit.*); purification through the barium salt, and recrystallisation from benzene-light petroleum afforded the acid; m. p. 120°. The silver salt (10 g.) was heated with iodine-free ethyl iodide (9·3 g.) and a few c.c. of absolute ether in a sealed tube for 1 hour at 100°; the mass was extracted with ether, and the residue distilled in a vacuum; b. p. 156—157°/15 mm. (yield, 2 g.).

Methyl *p*-bromo- $\beta$ -phenylpropionate. The acid (8 g.) (Glaser, *Annalen*, 1867, 143, 341; from methyl alcohol, m. p. 136°) was esterified with diazomethane (2 g.) in ether, affording the ester in quantitative yield; b. p. 154—155°/16 mm. (Found : C, 49·6; H, 4·8.  $C_{10}H_{11}O_2Br$  requires C, 49·4; H, 4·5%).

Ethyl *p*-phenylbenzoate. 4-Acetyl diphenyl (J. Amer. Chem. Soc., 1930, 52, 3718) (30 g.), potassium hydroxide (18 g.), potassium permanganate (96 g.), and water (1 l.) were boiled for 3 hours; the colourless liquid was immediately filtered and acidified, affording 17 g. of *p*-phenylbenzoic acid, m. p. 210°. The acid (30 g.) was boiled with thionyl chloride (120 g.) for 5 hours, the excess chloride distilled off, and the acid chloride recrystallised from light petroleum, forming clusters of needles, m. p. 112° (24 g.) [Found (method of Baubigny) : Cl, 16·6.  $C_{18}H_9OCl$  requires Cl, 16·2%]. It (7·5 g.) was treated with alcohol (40 c.c.) at room temperature (24 hours), and the solution boiled, filtered, and cooled, the resulting leaflets being recrystallised from light petroleum; m. p. 45°.

Measurements.—In the following tables,  $c$  = molar fraction,  $\bar{M}$  = average molecular weight of the solution,  $\zeta$  = density,  $\epsilon$  = dielectric constant,  $n$  = refractive index,  $P_t$  ( $P_{E_t}$ ) = total (electronic) polarisation of the solution,  $P$  ( $P_E$ ) = the same for the solute,  $P_{A+0}$  = (atomic and) orientation polarisation, which is extrapolated graphically for infinite dilution. Most of the experiments were carried out in benzene as solvent. The dipole moment of *p,p'*-dibromo-

benzylideneacetophenone was determined in dioxan, that of *pp'*-dinitrostilbene, m. p. 285°, in  $\alpha$ -methylnaphthalene. The physical constants of dioxan were taken from the data of Williams (*J. Amer. Chem. Soc.*, 1930, **52**, 1831, 1838; see Bergmann and Schuetz, *Z. physikal. Chem.*, 1932, **B**, **19**, 395) and from unpublished work done in our laboratory. The data for  $\alpha$ -methyl-naphthalene are due to Bergmann and Schuetz (*loc. cit.*). The experiments were made partly in collaboration with Dr. W. Schuetz.
