## Crystal and Molecular Structure of 15-Bromolongibornane-8,9-dione $\dagger$

#### Abstract

By Tayur N. Guru Row and Kailasam Venkatesan,* Department of Organic Chemistry, Indian Institute of Science, Bangalore 560012, India

The crystal and molecular structure of the title compound (1) has been determined by the heavy-atom method from 1038 observed three-dimensional photographic data. Crystals are orthorhombic. with $a=20.07 \pm 0.02 . b=10.05$ $\pm 0.02 . c=7.31 \pm 0.01 \AA$. space group $P 2_{12} 2_{1}{ }_{1}$. with $Z=4$. The structure was refined by block-diagonal leastsquares to $R 0.099$. The conformation of the norbornane moiety is discussed. The seven-membered ring portion of the molecule adopts an approximate chair conformation. The packing of the molecules in the crystal is mainly a consequence of van der Waals interactions.

While studying the acid rearrangement of a bromoderivative of the sesquiterpene longifolene a novel rearrangement product was obtained. ${ }^{1}$ On the basis of spectral evidences (i.r. and n.m.r.) a number of structures were suggested. An unambiguous determination

(1)
of the structure by $X$-ray crystallography was considered important as the rearrangement path for the compound was expected to have interesting mechanistic implications. Further the determination of the structure as (1) provided additional information regarding the geometry of the norbornane system.
$\dagger$ Systematic name 1-bromomethyl-2,6,6-trimethyltricyclo[5.3.1. $0^{2,8}$ ]undecane-3,4-dione.

## EXPERIMENTAL

Crystal Data. $-\mathrm{C}_{15} \mathrm{H}_{21} \mathrm{O}_{2} \mathrm{Br}, \quad M=313$. Orthorhombic, $a=20.07 \pm 0.02, \quad b=10.05 \pm 0.02, c=7.31 \pm 0.01 \AA$, $D_{\mathrm{m}}$ (by flotation) $=1.41 \mathrm{~g} \mathrm{~cm}^{-3}, Z=4, D_{\mathrm{c}}=1.43 \mathrm{~g} \mathrm{~cm}^{-3}$. Space group $P 2_{1} 2_{1} 2_{1}\left(D_{2}^{4}\right.$, No. 19), from systematic absences. $\mathrm{Cu}-K_{\alpha}$ radiation, $\lambda=1.5418 \AA ; \mu\left(\mathrm{Cu}-K_{\alpha}\right)=41.9 \mathrm{~cm}^{-1}$.

Unit-cell data were obtained from rotation and Weissenberg photographs taken with $\mathrm{Cu}-K_{\alpha}$ radiation. Threedimensional intensity data were collected by use of $\mathrm{Cu}-K_{\alpha}$ radiation for the layers $h k 0-6$ with rotation along the $c$ axis. As the crystal was brittle, it was not possible to cut one suitable for data collection about another axis. Intensities were measured visually and corrected for Lorentz, polarization, and spot-shape factors. ${ }^{2}$ An approximate correction for absorption ${ }^{3}$ was made by assuming the crystal to be cylindrical ( $\mu r$ 1.00). Of 1281 reflections possible within the region surveyed, 1038 were measured, and placed on an approximate layer scale by Wilson plots. ${ }^{4}$

Structure Determination and Refinement.-A three-dimensional Patterson map enabled location of the bromine atom, and a Fourier map, phased on this revealed the remaining
${ }^{1}$ G. Mehta and S. K. Kapoor, Tetrahedron Letters, 1972, 715.

${ }^{4}$ A. J. C. Wilson, Nature, 1942, 150, 152.
non-hydrogen atom positions. Positional parameters, individual isotropic temperature parameters, and individual layer scale-factors were then refined. ${ }^{5}$ The quantity minimized was $\Sigma w\left(\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$, where $w$ is the weight of an observation. The distribution of $|\Delta F|^{2} v s$. $\left|F_{0}\right|$ suggested a weighting scheme ${ }^{6}$ of the form $w=1 / F_{\text {min. }}$ for $\left|F_{\mathrm{o}}\right| \leqslant\left|F_{\text {min. }}\right|$ and $w=1\left|F_{0}\right|$ for $\left|F_{0}\right|>\left|F_{\text {min. }}\right|$ with $F_{\text {min. }}$ 3.6. A threedimensional difference electron-density map computed at this stage ( $R 0.136$ ) showed peaks ranging from 0.3 to 0.7 $e \AA^{-3}$ at sites where hydrogen atoms were expected to be. Three cycles of refinement with anisotropic temperature factors for all non-hydrogen atoms and refining the overall scale-factor, gave $R \quad 0.099$ for all observed 1038 reflections. Hydrogen atoms were included in calculated positions (assuming $\mathrm{C}-\mathrm{H} 1.0 \AA$ ). The shifts in the parameters after the last cycle were $<0.1 \sigma$. In all structurefactor calculations, atom scattering factors for carbon, oxygen, and bromine were taken from ref. 7, and for hydrogen from ref. 8, those for bromine being corrected for the real part of anomalous dispersion $\left(\Delta f^{\prime}\right) .{ }^{9}$

Final positional and thermal parameters for non-hydrogen atoms are recorded in Table 1. Observed and calculated

structure-factors, calculated hydrogen atom positions, and anisotropic thermal parameters are listed in Supplementary Publication No. SUP 21313 ( 9 pp., 1 microfiche).*

## DISCUSSION

Description of the Structure.-The $X$-ray investigations showed the structure to have the structure (1) as shown in Figure 1. Bond lengths and angles and their standard derivations are recorded in Table (2). The $\mathrm{C}-\mathrm{Br}$ distance ( $1.952 \AA$ ) is in good agreement with the usual value for a $\mathrm{C}\left(s p^{3}\right)-\mathrm{Br}$ bond. ${ }^{10}$ The mean $\mathrm{C}-\mathrm{C}$ bond length within the bicyclic moiety ( $1.569 \pm 0.018 \AA$ )

[^0]compares well with the value observed in other structures containing this system. ${ }^{11,12}$ Electron diffraction studies ${ }^{13}$ on a substituted norbornane system show a mean bond length of $1.550 \pm 0.015 \AA$. However in the present

Figure 1 A view of the molecule
structure the $\mathrm{C}(1)-\mathrm{C}(6)$ and $\mathrm{C}(2)-\mathrm{C}(3)$ bond lengths are equal, mean $1.508 \AA$, which is much shorter than the other $\mathrm{C}-\mathrm{C}$ bonds in the norbornane system. All internal angles in the norbornane system are less than the tetrahedral value ( $109.5^{\circ}$ ), the apex angle $\mathrm{C}(3)-\mathrm{C}(7)-\mathrm{C}(6)$ being as small as $95.1(9)^{\circ}$. These features are consistent with the situation observed from $X$-ray investigations of other

Figure 2 Newman projection down the $C(3) \cdots C(6)$ vector
norbornanes as well as with the values obtained via molecular mechanics calculations. ${ }^{14,15}$ In the seven-membered ring all internal angles at $s p^{3}$ hybridized carbon atoms, with the exception of $C(1)-C(6)-C(7)$, are larger than the tetrahedral value, mean $113.6(8)^{\circ}$, but the value at the $s p^{2}$ hybridized carbon atoms $C(8)$ and $C(9)$ is not different from the expected $120^{\circ}$. No significance can be attached to the variations in the $\mathrm{C}\left(s p^{3}\right)-\mathrm{C}\left(s p^{3}\right)$ bonds in the sevenmembered ring, especially since the thermal vibrations of the atoms of this ring are much greater than those of the

[^1]norbornane system. The $\mathrm{C}(8)-0(1)$ and $\mathrm{C}(9)-\mathrm{O}(2)$ bond distances ( 1.250 and $1.235 \AA$ ) are in agreement with the value ( $1.25 \AA$ ) observed in carboxylate ions. ${ }^{16}$
torsion angles within the norbornane moiety compare well with values obtained in ref. 14 from theoretical calculations. ${ }^{14}$ The difference between the torsion angles

$\mathrm{C}(7)-\mathrm{C}(3)-\mathrm{C}(4)-\mathrm{C}(5)$ and $\mathrm{C}(7)-\mathrm{C}(6)-\mathrm{C}(5)-\mathrm{C}(4)$ is zero in a structure possessing $C_{2 v}$ symmetry. In order to study the nature of the pseudorotation of the norbornane system a

Newman projection down the non-bonded vector C(3) ... $C(6)$ is shown in Figure 2. According to the numbering system of ref. 14 the twist is synchro- $S(+,+)$.

The energy minimization calculations of Bixon and Lifson ${ }^{17}$ show that the energetically favourable conformation of a cyclo-heptane ring are skew chair, chair, boat, and skew boat with energies $5.55,6.22,7.95$, and 8.19 $\mathrm{kcal} \mathrm{mol}{ }^{-1}$. The present seven-membered ring corresponds very nearly to a chair conformation. It is interesting that the conformation of the seven-membered ring in longifolene hydrochloride ${ }^{12}$ is the same as in the present structure, which has two carbonyl groups, whereas these are not present in the former.

The packing of the molecules in the unit cell is illustrated in Figure 3. The structure is stabilised mainly by van der Waals interactions.

We thank Dr. G. Mehta, Department of Chemistry, Indian Institute of Technology, Kanpur for crystals and useful discussions, and the C.S.I.R. (India) for financial assistance (to T. N. G.).
