

### Aqueous Dissociation of Dihydroxycyclopropenone (Deltic Acid)

By **Robert I. Gelb** and **Lowell M. Schwartz**,\* Department of Chemistry, University of Massachusetts, Boston, Massachusetts, U.S.A.

Deltic acid ( $\text{H}_2\text{C}_3\text{O}_3$ ) dissociates in water with  $\text{p}K_1 2.57 \pm 0.04$  and  $\text{p}K_2 6.03 \pm 0.06$  at  $25^\circ$ , which values indicate it is a considerably weaker acid than the other series members dihydroxycyclobutenedione ( $\text{H}_2\text{C}_4\text{O}_4$ ) and dihydroxycyclopentenetrione ( $\text{H}_2\text{C}_5\text{O}_5$ ).

A RECENT synthesis of dihydroxycyclopropenone<sup>1</sup> (deltic acid,  $\text{H}_2\text{C}_3\text{O}_3$ ) has provided the three-carbon member of the cyclic oxocarbon acid series of which the anions are noted for their aromatic character<sup>2</sup> and some of the

$0.80 \pm 0.08$ ,<sup>5</sup>  $pK_2$   $2.24 \pm 0.01$ .<sup>5</sup> To discover if the high acid strength extends to deltic acid we have made pH potentiometric titrations of aqueous solutions of both deltic acid with NaOH and the salt  $\text{Li}_2\text{C}_3\text{O}_3$  with HCl.

#### EXPERIMENTAL

Samples of both  $\text{H}_2\text{C}_3\text{O}_3$  and  $\text{Li}_2\text{C}_3\text{O}_3$  were generously supplied by D. Eggerding and R. West of the University of Wisconsin. Their synthesis of  $\text{H}_2\text{C}_3\text{O}_3$  is reported elsewhere<sup>1</sup> and  $\text{Li}_2\text{C}_3\text{O}_3$  was prepared by reaction of bis(trimethylsiloxy)cyclopropenone with lithium *t*-butoxide.<sup>6</sup> We used these samples without purification. The titration endpoints revealed that the lithium salt was monohydrated and that the sample contained *ca.* 5% of a basic impurity, while deltic acid was anhydrous and free of impurity to within the accuracy of our equivalent weight determinations. An Orion model 801 digital pH meter was equipped with micro-glass and micro-calomel electrodes and standardized by a 'two buffer' method using 0.1M-HCl and a 1:1 phosphate mixture.<sup>7</sup> In a typical experiment, the meter was standardized at the appropriate temperature by utilizing measured portion of the buffer in a cell thermostatted to  $\pm 0.2^\circ$ . The meter standardization was rechecked at the completion of each experiment and seldom differed from the initial settings by more than 0.005 pH units. Titrations of  $\text{H}_2\text{C}_3\text{O}_3$  were carried out between 15 and  $35^\circ$  with some decomposition being noted at 30 and  $35^\circ$  but not at 25 or less within *ca.* 3 h. An attempted titration at  $45^\circ$  resulted in decomposition within minutes. One  $\text{H}_2\text{C}_3\text{O}_3$  sample at  $25^\circ$  was titrated beyond the second equivalence point with NaOH, then back titrated with an excess of HCl, and then back again with NaOH. The stability of deltic acid and its anions was established at this temperature in that the three  $pK_1$  and  $pK_2$  values calculated from these data were in agreement to within 0.01 and 0.06, respectively.

#### RESULTS AND DISCUSSION

The  $pK$  values were calculated from the well known stoichiometric and equilibrium relationships of a dibasic acid in aqueous solution. Concentrations were expressed as molarities and molar activity coefficients of ionic species were estimated using the Debye-Hückel equation with ion-size parameters of 4.5 and 9 Å for deltatate anions and hydronium, respectively. The temperature dependencies of the other Debye-Hückel parameters were taken from the Robinson and Stokes<sup>8</sup> tabulation.  $pK$  values were calculated for solutions corresponding to each recorded pH and volume. Since the  $pK$  values for the primary and secondary dissociations were sufficiently well separated, it was possible to derive  $pK_1$  values solely from solutions before the first equivalence point in the  $\text{H}_2\text{C}_3\text{O}_3$  titration (or between the two equivalence points in the  $\text{Li}_2\text{C}_3\text{O}_3$  titration) and to derive  $pK_2$  from solutions between the  $\text{H}_2\text{C}_3\text{O}_3$  titration equivalence points (or before the first equivalence point of the  $\text{Li}_2\text{C}_3\text{O}_3$  titration). In any case, an iterative calculation was required to solve the set of equations to determine ionic strength, activity coefficients, and hydronium concentration in each solution from the pH and solution

volume. It was apparent from an inflection at the beginning of the titration that the  $\text{Li}_2\text{C}_3\text{O}_3$  sample contained a basic impurity amounting to *ca.* 5%. Since the small quantity of material available to us precluded a purification step, we deduced from the initial pH values that the identity of the impurity was lithium carbonate and thus compensated each solution calculation for the presence of carbonate-carbonic acid equilibria. The ultimate justification for this procedure is that  $pK$  values calculated in this manner were in close agreement with  $pK$  values calculated from the  $\text{H}_2\text{C}_3\text{O}_3$  titrations for which impurity compensation was not necessary. In a manner described previously,<sup>5</sup> maximum probable uncertainties were calculated for the computed  $pK$  values by estimating sources of determinate and/or random errors in the experimental data and the activity coefficient correlations. This estimate yielded  $\pm 0.04$  and  $\pm 0.06$  for  $pK_1$  and  $pK_2$ , respectively.

The results are shown in Table 1. Although the trend

of  $pK$  values with temperature is not clear, it appears that  $pK_1$  may be at a minimum near  $25^\circ$  and that  $pK_2$  is virtually independent of temperature over the experimental range. If these conclusions are true, then the standard enthalpies of both dissociations are nearly zero, which value leads to estimates of the standard entropies of dissociation of  $-12$  and  $-27 \text{ cal mol}^{-1} \text{ K}^{-1}$  for the first and second dissociation, respectively. In Table 2, these values are shown in comparison to the corresponding thermodynamic quantities of the four and five carbon homologues. Deltic acid is a decidedly weaker acid in both dissociations. From our  $\Delta H_2^\circ$  and  $\Delta S_2^\circ$  values for deltic acid, it appears that the more positive enthalpy

change compared with  $\text{H}_2\text{C}_4\text{O}_4$  and  $\text{H}_2\text{C}_5\text{O}_5$  is the main reason for the weaker second dissociation. This may be caused by a decreased stability of the deltatate dianion due to ring strain. On the other hand,  $\text{p}K_1$  of deltic acid is larger than that of  $\text{H}_2\text{C}_4\text{O}_4$  or  $\text{H}_2\text{C}_5\text{O}_5$  because of a more negative  $\Delta S_1^\circ$  value. The more positive  $\Delta S_1^\circ$  values of  $\text{H}_2\text{C}_4\text{O}_4$  and  $\text{H}_2\text{C}_5\text{O}_5$  have been attributed to the two effects: (a) an unusually high degree of water

structuring around the uncharged acid molecules or (b) an unusually low degree of water structuring around the monoanions perhaps as a result of charge delocalization. The trend of increasing  $\Delta S_1^\circ$  with increasing ring size favours the latter of these effects. However the  $\Delta S_1^\circ$  values, themselves, seem abnormally positive, which might be ascribed to the former effect.
