An adaptation of characteristic vector analysis has been applied to incomplete u.v. spectral data of a very weak base only partially protonated in pure sulphuric acid, 3-cyano-5,5-dimethylcyclohex-2-en-1-one (1). The estimated  $pK_{BH^+}$  value,  $-5.29$ , obtained from the  $H_A$  acidity function is in very good agreement with those calculated from linear free energy relationships:  $pK_{BH^+}$  vs.  $\sigma^+$  ( $-4.96$ ) or  $pK_{BH^+}$  vs.  $\sigma_I$ ,  $\sigma_R^+$  ( $-4.93$ ) and the extra-thermodynamic relationship of  $pK_{BH^+}$  vs.  $\Delta H_{BF_3}^\circ$  ( $-5.32$ ) for a series of 3-substituted-5,5-dimethylcyclohex-2-en-1-ones. This statistical method can be generalized for compounds in which the protonation is very incomplete even in pure sulphuric acid and for which the u.v.-visible spectral data are limited.

Evaluation of the relative basicities of weak organic bases B has attracted much interest both as a source of information about electronic structures and as a means of interpreting the reactivities of acid-catalysed reactions.<sup>1-6</sup> In the solution phase, the most common measure of basicity is the  $pK_{BH^+}$  of the conjugate acid  $BH^+$  of the base B [equation (1)].<sup>1</sup> If the main problem in evaluating thermodynamic  $pK_{BH^+}$  values in non-ideal media is the choice of methods to solve equation (2)<sup>7,8</sup>

$$pK_{BH^+} = \log I - \log C_{H^+} - \log(\gamma_B \gamma_{H^+} / \gamma_{BH^+}) \quad (2)$$

where  $I$  is the ionization ratio ( $C_{BH^+}/C_B$ ) and  $\gamma$  the molar activity coefficients, the first requirement for all methods is that measurements are made under conditions where significant amounts of the unprotonated and protonated forms of the base are present simultaneously in solution. Moreover, the characteristic parameters of the protonated form  $BH^+$  (for instance,  $\epsilon_{BH^+}$  for the u.v. method or  $\nu_{BH^+}$  for the n.m.r. method) often require the determination of the ionization ratio, whatever the spectroscopic method. However, obtaining of these parameters for a very weak base is sometimes difficult because the base is incompletely protonated even in 100%  $H_2SO_4$  or other acids. This problem frequently occurs with simple aliphatic ketones which are only 50% protonated in ca. 80%  $H_2SO_4$ , and the estimated  $pK_{BH^+}$  values of which differ considerably from those reported.<sup>9-12</sup> In the course of our study of Br nsted and Lewis basicities of cyclohexenones<sup>7,13-16</sup> we encountered this problem for compounds with strongly electron-withdrawing substituents on the ethylenic double bond, particularly for 3-cyano-5,5-dimethylcyclohex-2-en-1-one (1), for which 50% protonation was not observed in 98% sulphuric acid solution. The encouraging results we obtained using characteristic vector analysis (CVA) for the correction of 'medium effects' from u.v. spectral data<sup>7,17</sup> and for examination of acidity functions<sup>8</sup> prompted us to adapt this method to estimate the  $pK_{BH^+}$  value of (1) from very incomplete u.v. spectral data of this compound.

### Experimental

**Substrate.**—The preparation of 3-cyano-5,5-dimethylcyclohex-2-en-3-one (1) and its spectroscopic properties are described.<sup>18,19</sup>

**General Procedure for Spectrophotometric Basicity Determination.**—Methods for  $pK_{BH^+}$  measurement have been previously reported.<sup>7</sup>

**Principal Component Analysis of Spectra.**—The experimental u.v. spectra of sulphuric acid solutions of 3-cyano-5,5-dimethylcyclohex-2-en-1-one (1) presented in Figure 1 are very incomplete. Only the spectra 14-18 recorded in non-aqueous solutions with  $H_A < -5$  show shoulders in the long-wavelength region, which could be characteristic for the protonated form,  $BH^+$ , of the ketone (1). The ionization ratio  $I = [B]/[BH^+]$  could not be calculated from such spectral data, even using CVA-TCA procedure,<sup>17</sup> because the range of the magnitude  $A_{BH^+}$  is not known. We attempted to overcome this serious problem using principal component analysis (PCA) procedures, claimed as the method for the calculation of physical responses of two pure forms from data obtained from mixtures of the two components.<sup>20,21</sup> The first objective of PCA

**Figure 1.** Experimental absorbances of (1) as a function of sulphuric acid acidity ( $H_A$ ). Solvent numbers (top to bottom at  $\lambda_{max} = 240$ ) and  $H_A$  are: (1)  $+1.00$ ; (2)  $+0.09$ ; (3)  $-0.92$ ; (4)  $-1.64$ ; (5)  $-2.14$ ; (6)  $-2.64$ ; (7)  $-3.01$ ; (8)  $-3.45$ ; (9)  $-3.86$ ; (10)  $-4.30$ ; (11)  $-4.32$ ; (12)  $-4.52$ ; (13)  $-4.75$ ; (14)  $-4.92$ ; (15)  $-4.99$ ; (16)  $-5.24$ ; (17)  $-5.42$ , and (18)  $-5.70$

or CVA is to obtain an 'abstract' solution, wherein all data are expressed as linear sums of product terms. The number of terms is called the number of components (or vectors). The standard PCA or CVA procedures applied to the digitalized set of spectra shown in Figure 1 indicate two principal components accounting for 99.50% of total data variability. Thus any absorbance  $A_{n,p}$  could be represented by the following equation:

$$A_{n,p} = C_{1,p} L_{n,1} + C_{2,p} L_{n,2} \quad (3)$$

In this equation  $C$  represents the principal component for wavelength  $p$ , and  $L$  represents the loading for the  $n$ th spectrum. The 'abstract' solution is purely mathematical and is devoid of physical meaning; however we can reconstitute the new family of absorption spectra, as shown in Figure 2. The isobestic point is now much more clearly defined and the maximum of spectrum 18 is shifted towards the long-wavelength region characteristic for protonated base.

The ultimate objective of PCA is to convert the 'abstract' solution into a real solution and to develop a meaningful model based on the data. Transformation of the 'abstract' solution, which is presented as a plot of orthogonal principal components  $C_{1,p}$  vs.  $C_{2,p}$  in Figure 3, into real spectra is achieved by

Figure 2. Reconstituted absorbances of (1). For further details see Figure 1

Figure 3. The 'abstract' solution as a plot of principal components.  $D$ ,  $E$ , and  $G$  are the oblique axes (see text). The numbers refer to wavelengths in the region 220–310 nm at 5 nm intervals

determining the new oblique axes. It was proposed<sup>20</sup> that the asymptotes  $D, E$  starting from origin would enable us to find the real solution under certain conditions: (i) absorbances (and concentrations) of both components,  $B$  and  $BH^+$  being non-negative, and (ii) the absorbance of each component reaches zero, at the wavelength equivalent to the tangential point. The real components  $C_{D,p}$  and  $C_{E,p}$ , and equivalent loadings allow us to calculate the spectra of  $BH^+$  and  $B$ , respectively. The second condition however has been discarded<sup>21</sup> and replaced by the highest dissimilarity of real spectra (HDRS).

## Results and Discussion

Both procedures<sup>20,21</sup> give good approximations of the pure base spectrum  $B$ . The shape of the absorption band is regular with  $\lambda_{max}$  246 nm and absorbance  $A_B$  0.665. The absorbance is lower than for spectra 1–6. This means that the base under study undergoes solvation in highly aqueous solutions rather than measurable protonation. Such an explanation is rational and obvious.<sup>22</sup> However the procedures<sup>20</sup> fail, in our opinion, to predict the spectrum of the ion  $BH^+$ . The projection of abstract principal components on the oblique axis  $E$  yields the spectrum of  $BH^+$  with  $A = 0$  at  $\lambda$  242.5 and 275 nm with very high absorbance (1.1). The shape of this spectrum is rather strange especially in the short-wavelength region.

We believe that the HDRS procedure,<sup>21</sup> in which the projection axis for  $BH^+$  would be beyond the axis  $E$  and must fulfill the conditions  $|\lambda_{max}^B - \lambda_{max}^{BH^+}| = \max$  and  $A_{BH^+} > 0$ , gives good results. The best solution was found with axes  $D$  and  $G$  ( $\angle G-O-PC1 = 11.5^\circ$ ), and the spectra of  $B$  and  $BH^+$  calculated from these are presented in Figure 4.

The ionization ratio and  $pK_{BH^+}$  value were calculated using the 'generalized Hammett method' described previously,<sup>7</sup> and supported by earlier works.<sup>13,23,24</sup> Two  $\lambda_{max}$  values were used:  $\lambda_B$  245 and  $\lambda_{BH^+}$  270 nm to calculate  $\Delta A_B$ ,  $\Delta A_{BH^+}$ , and  $\Delta A_n$  where  $\Delta A$  is the difference in optical density in  $\lambda_B$  and  $\lambda_{BH^+}$  for the appropriate spectra. Thus the ionization ratio  $I$  and  $pK_{BH^+}$  were calculated from equations (4) and (5). The  $H_A$  acidity

$$I = (\Delta A_{BH^+} - \Delta A_n) / (\Delta A_n - \Delta A_B) \quad (4)$$

$$pK_{BH^+} = H_A + \log I \quad (5)$$

function corrected by Edward and Wong<sup>25</sup> was used. The main results are presented in the Table.

Figure 4. Calculated spectra of  $B$  and  $BH^+$

**Table.** Abbreviated experimental data for the  $pK_{BH^+}$  calculation

Spectrum	$-H_A$	$\Delta A_n^a$	$\log I$	$pK_{BH^+}$
B		-0.4994 <sup>b</sup>		
9	4.3024	-0.4049	-0.9852	-5.2876
10	4.3204	-0.3987	-0.9546	-5.2750
11	4.5233	-0.3335	-0.7054	-5.2287
12	4.7475	-0.2556	-0.4960	-5.2435
13	4.9233	-0.1959	-0.3656	-5.2889
14	4.9899	-0.1701	-0.3139	-5.3004
BH <sup>+</sup>		0.5084 <sup>c</sup>		
mean				-5.27 ± 0.03

<sup>a</sup>  $\Delta A_n = A_{n,p=275\text{nm}} - A_{n,p=240\text{nm}}$ . <sup>b</sup>  $\Delta A_B$  calculated using  $A_{B,p=275\text{nm}} = 0.1524$ ,  $A_{B,p=240\text{nm}} = 0.6518$ . <sup>c</sup>  $\Delta A_{BH^+}$  calculated using  $A_{BH^+,p=275\text{nm}} = 0.7448$ ,  $A_{BH^+,p=240\text{nm}} = 0.2364$ .

The mean value found for  $pK_{BH^+}$  was -5.27 units, standard deviation ±0.03. The slope of the straight line

$$\log I = -mH_A + b \quad (6)$$

$m = 0.97 \pm 0.05$  means that the amide acidity function  $H_A$  describes the protonation of (1) correctly. The intercept  $b$ , -5.29 (the value of  $H_A$  at 50% protonation,  $c_B = c_{BH^+}$ ), is in close agreement with  $pK_{BH^+}$ .

The calculated value of  $pK_{BH^+}$  (-5.27) is in fairly good agreement with that calculated from LFER based on  $\sigma^+$  substituent constant (-4.96) or on  $\sigma_I$  and  $\sigma_R^+$  substituent constants (4.93) and in very good agreement with that estimated from the extra-thermodynamic relationship using the  $\Delta H_{BF}^\circ$ , basicity parameter (-5.32) for similar cyclohexenones.<sup>16</sup>
