## Crystallographic Studies of the Boron-Nitrogen Bond in Aminoboranes. Part IV. ${ }^{1}$ Crystal and Molecular Structure of (Diphenylmethyleneamino)dimesitylborane

By Graham J. Bullen, Department of Chemistry, University of Essex, Colchester CO4 3SO
Crystals of the title compound are orthorhombic, $a=17 \cdot 36, b=29 \cdot 25, c=10 \cdot 12 \AA$, space group Pbca, $Z=8$. Their structure was determined from diffractometer $X$-ray intensity data by direct methods and refined by fullmatrix least squares to $R 0.078$ for 608 reflexions. The $>\mathrm{B} \leftrightarrows \mathrm{N}=\mathrm{C}<$ system in the molecule has an allene-type geometry with $\mathrm{B} \leftarrow \mathrm{N} 1 \cdot 38(2), \mathrm{C}=\mathrm{N} 1 \cdot 29(2) \AA$, and $\mathrm{B}-\mathrm{N}-\mathrm{C}$ of $173(2)^{\circ}$. Bond orders obtained by MO calculations are: $B \leftrightarrows N 1 \cdot 6, C=N 1 \cdot 8$. The mean $B-C$ bond length is $1 \cdot 59(2) \AA$. The mesityl and phenyl groups are rotated from the position eclipsed with the $B \longleftarrow N$ or $C=N$ bonds, the torsion angles being: $C-C-B-N-51$ and -65 , and $\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{N} 29$ and $50^{\circ}$.

The aim of previous papers in this series has been to demonstrate, by determination of stereochemistry, that in aminoboranes there is a significant degree of $\mathrm{B} \leftrightarrows \mathrm{N}$
${ }^{1}$ Part III, G. J. Bullen and P. R. Mallinson, J. Chem. Soc. (A), 1970, 2213.
dative $\pi$-bonding. It was shown in particular that in a $>\mathrm{B} \leftrightarrows \mathrm{N}<$ system the environment of the three-coordinate nitrogen atom is trigonal planar, the most striking example of this being the completely planar molecule of tri-(1,3,2-benzodioxaborol-2-yl)amine (I). ${ }^{1}$

Recently a number of monomeric aldimino- and ketiminoboranes, in which the nitrogen linked to boron is only

(1)
two-co-ordinate, have been prepared. ${ }^{2-5}$ I.r. and n.m.r. measurements indicate that $\mathrm{B} \leftarrow \mathrm{N}$ dative $\pi$-bonding also occurs in these compounds and that consequently the cumulative $\mathrm{B} \leftrightarrows \mathrm{N}=\mathrm{C}$ system should be linear as is the isoelectronic $\mathrm{C}=\mathrm{C}=\mathrm{C}$ system in allene. Since geometrically the difference between linear $\leftarrow \mathrm{N}=$ and bent $-\dot{\mathrm{N}}=$ systems is much clearer than the difference between planar $\leftrightarrows \mathrm{N}<$ and pyramidal $-\dot{\mathrm{N}}<$, determination of the molecular structure of an aminoborane containing two-co-ordinate nitrogen could provide even more convincing proof of $\mathrm{B} \leftarrow \mathrm{N}$ dative $\pi$-bonding than from previous studies. It was therefore decided to investigate the crystal structure of (diphenylmethyleneamino)dimesitylborane (II). The i.r. spectrum of this compound shows

(II)
a band at $1792 \mathrm{~cm}^{-1}$, attributed to the asymmetric stretching frequency of a cumulative $\mathrm{B} \leftrightarrows \mathrm{N}=\mathrm{C}$ system. ${ }^{4}$ By contrast a $B-\dot{\mathrm{N}}=\mathrm{C}$ system would be expected ${ }^{6}$ to have $v(\mathrm{C}=\mathrm{N})$ in the region of $1590-1690 \mathrm{~cm}^{-1}$. Higher stretching frequencies are characteristic of cumulative $\pi$-systems $\left[\right.$ e.g. $v_{\text {as }}(\mathrm{C}=\mathrm{C}=\mathrm{C})$ at $1920-2000,{ }^{7}$ or $v_{\mathrm{as}}(\mathrm{C}=\mathrm{N}=\mathrm{C})$ at $c a .1845 \mathrm{~cm}^{-1}$ (ref. 8)]. Molecule (II) offers the possibility of a high $\mathrm{B}-\mathrm{N}$ bond-order because the donor and acceptor abilities of the nitrogen and boron atoms are confined to one bond.

$D_{\mathrm{c}}=1 \cdot 11, Z=8, D_{\mathrm{m}}=1.08$ (by flotation), $F(000)=$ 1840. $\mu=0.72 \mathrm{~cm}^{-1}$ for Mo- $K_{\alpha}$ radiation, $\lambda=0.7107 \AA$. Space group Pbca (No. 61) from systematic absences: $0 k l$ for $k$ odd, $h 0 l$ for $l$ odd, $h k 0$ for $h$ odd; Laue symmetry $m m m$.

The crystals were thin flakes parallel to (010) and elongated along $c$. As a precaution against attack by atmospheric moisture (although the substance is reported to be airstable ${ }^{4}$ ) they were sealed inside thin-walled glass capillaries for the $X$-ray examination. Unit-cell dimensions were measured from precession photographs (Mo- $K_{\alpha}$ radiation). $X$-Ray intensities were measured on a Philips PAILRED diffractometer with monochromatised $\mathrm{Mo}-K_{\alpha}$ radiation. The diffraction pattern was weak, statistically significant intensities [with $I>2 \sigma(I)$ ] being obtained for only 608 independent reflexions out of 2540 measured in the region out to $\sin \theta / \lambda 0 \cdot 5$. The intensities of the $00 l$ reflexions could not be measured as the crystal was aligned with its $c$ axis parallel to the capillary length and this was placed parallel to the $\omega$ axis of the diffractometer, but it was clear from $X$-ray photographs that only three $00 l$ reflexions of significance were thereby missed. The intensities were corrected for Lorentz and polarisation effects but not for absorption, the linear absorption coefficient being very small.

The sign-determination calculations were carried out at the Atlas Computer Laboratory, Chilton, by use of the ' $X$-Ray ' programme package, and the least-squares refinement on the University of Essex PDP 10 computer with a programme written by Dr. G. M. Sheldrick. Atomic scattering factors were calculated by the analytic function $f=C+$ $\sum_{i=1}^{4} A_{i} \exp \left(-B_{i} \sin ^{2} \theta / \lambda^{2}\right)$, the parameters $A, B$, and $C$ being taken from ref. 9 for nitrogen, carbon, and boron, and from ref. 10 for hydrogen.

Structure Determination.-The use of Wilson plots to obtain the absolute scale of the $X$-ray intensities and the average temperature factor gave only very approximate values because the plots were curved. Normalised structure factors were calculated and the values of the scale factor and mean temperature factor were adjusted to make the mean $E^{2}$ equal to 1 . For the $|E|$ values so obtained, $0.8 \%$ of the reflexions had $|E|>3$ and $21 \%$ had $|E|>1$, an unusual distribution since the theoretical prediction is 0.3 and $32 \%$ respectively for a random but centrosymmetric arrangement of atoms. ${ }^{11}$ This discrepancy is perhaps to be expected because a molecule containing four benzene rings has a considerable degree of order in its atomic arrangement.
$\Sigma_{2}$ Sign relationships were used to determine the signs of 144 reflexions whose $|E|$ values were $>1.5$ [these included three reflexions used to define the origin and one reflexion $(0,24,0)$ whose sign was indicated by a number of $\Sigma_{1}$ relationships]. An $E$ map calculated with these signs revealed the nitrogen atom and 30 out of the 31 carbon atom positions. The atoms of phenyl group (ii) (for numbering system see Figure 1) were less distinct in the $E$ map than the other atoms and for this reason three of them were at first placed incorrectly. This relative weakness of phenyl

group (ii) persisted in subsequent Fourier syntheses and is related to the large thermal factors eventually found for these atoms. An electron-density synthesis calculated with 397 reflexions revealed the remaining carbon atom and the boron position and also showed that phenyl group (ii) had been orientated incorrectly. In the subsequent leastsquares refinement, hydrogen atoms were incorporated in the calculations. Those in the benzene rings were placed at calculated positions assuming $\mathrm{C}-\mathrm{H} 1.05 \AA$ and those in the methyl groups were located from a difference-Fourier synthesis with subsequent slight adjustment of position to give reasonable bond lengths and angles in the methyl group. By use of individual isotropic temperature factors and unit weights, $R$ was thus reduced to 0.092 for the 608 reflexions. It was not considered worthwhile to refine the temperature factors of all boron, nitrogen, and carbon atoms anisotropically since this would have produced 299 variables to be refined with only 608 reflexions. However it was noted that the temperature factors of the carbon atoms in phenyl group (ii) were large, with $\overline{u^{2}}$ up to $0.13 \AA^{2}$, and furthermore when anisotropy was introduced for these atoms, refinement showed it to be considerable. The possibility was considered that the cause of the large temperature factors (and large anisotropy) of this group of atoms was that the position of the group was disordered, possibly by rotation around the $\mathrm{C}(31)-\mathrm{C}(7)$ bond. To test this a difference-Fourier synthesis, from which atoms $\mathrm{C}(8)$ (12) and $\mathrm{H}(8)$-(12) were omitted, was examined for peaks in positions other than those already postulated. None was found but the peaks present were considerably spread out, in agreement with the high temperature factors. The hypothesis of disorder was therefore rejected and it was concluded that the high temperature factors represent a real vibration effect. Support for this was provided by the fact that the maximum vibrations of atoms $\mathrm{C}(7)$-(12) lay in approximately the same direction [parallel to the $\mathrm{C}(9) \cdots$ $\mathrm{C}(11)$ line] and that the thermal parameters increased in the order $\mathrm{C}(7)<[\mathrm{C}(8), \mathrm{C}(12)]<[\mathrm{C}(9), \mathrm{C}(10), \mathrm{C}(11)]$. This suggests that this phenyl group is undergoing large oscillations about an axis perpendicular to the ring and lying outside it, probably in the region of $\mathrm{C}(31)$. The connexion between this and the packing of the molecules is discussed on p. 862.

It was therefore considered necessary to retain anisotropic temperature factors for atoms $\mathrm{C}(7)$-(12) in carrying out four further cycles of full-matrix least-squares refinement but, in order to reduce the number of variables, all other atoms were refined isotropically (except hydrogen for which no parameters were refined). The function minimised was $\Sigma w \Delta^{2}$ where $\Delta=\left|F_{0}\right|-\left|F_{\mathrm{c}}\right|$. The weighting scheme $w=$ 1 for $\left|F_{0}\right| \leqslant A$ and $w=\left(A /\left|F_{0}\right|\right)^{2}$ for $\left|F_{0}\right|>A$ was used, $A$ being ultimately given the value 85 on absolute scale, to produce similar mean values of $w \Delta^{2}$ for ranges of increasing $\left|F_{0}\right|$ or $\sin \theta / \lambda$. During this refinement the temperature factors of $C(7), C(8)$, and $C(10)$ became non-positive definite and their values had to be fixed during the final cycle of refinement. In this cycle all parameter shifts were $<0 \cdot 1 \sigma$. The final $R$ is 0.078 for 608 reflexions, and $R^{\prime}\left[=\left(\Sigma w \Delta^{2} / \Sigma w-\right.\right.$ $\left.\left.\left|F_{0}\right|^{2}\right)^{\frac{1}{2}}\right]$ is 0.097 .

## RESULTS AND DISCUSSION

Final atomic co-ordinates and thermal vibration parameters are listed in Tables 1 and 2. The coordinates and thermal parameters used for the hydrogen atoms are given in Table 3. Observed and calculated
structure factors are listed in Supplementary Publication No. SUP 20653 ( 5 pp., 1 microfiche).* Bond lengths and bond angles are given in Figure 1 together with their estimated standard deviations calculated by use of the

full covariance matrix. The molecular shape is shown in Figure 2.
$\pi$-Bonding between the boron and nitrogen atoms producing a $\mathrm{B} \longleftarrow \mathrm{N}=\mathrm{C}$ system analogous to the $\mathrm{C}=\mathrm{C}=\mathrm{C}$ in allene is indicated by the following features of the molecular geometry: the $\mathrm{B}-\mathrm{N}-\mathrm{C}$ angle is close to $180^{\circ}$, the $\mathrm{B}-\mathrm{N}$ bond is short, and the planar groupings $\mathrm{C}(13)^{-}$ $\mathrm{C}(19)-\mathrm{B}-\mathrm{N}$ and $\mathrm{C}(\mathrm{l})-\mathrm{C}(7)-\mathrm{C}(31)-\mathrm{N}$ are very nearly mutually perpendicular (dihedral angle $86^{\circ}$, see Table 4 for equations of planes). The mesityl groups are pre-

* For details see Notice to Authors No. 7 in J. Chem. Soc. (A), 1970, Issue No. 20.
vented by steric hindrance from being coplanar with the neighbouring trigonal grouping at the boron atom (Figure 2). Likewise the phenyl groups are not coplanar with the trigonal grouping around $\mathrm{C}(31)$. The torsion angles of these groups (measured as the angles between

Length and Order of the $\mathrm{B}-\mathrm{N}$ Bond.-The $\mathrm{B}-\mathrm{N}$ bond length ( $1.38 \AA$ ) is one of the shortest found in aminoboranes [cf. 1.40 and 1.43 in $\mathrm{Me}_{2} \mathrm{NBMe}_{2}{ }^{12} 1.41$ in $B$ trichloroborazole, ${ }^{13}$ and 1.387 and $1.407 \AA$ in $\left(\mathrm{Me}_{2}-\right.$ $\left.\left.\mathrm{NBCH}_{2}\right)_{3}{ }^{14}\right]$. The bond order corresponding to this

All atoms are carbon unless marked otherwise, and the atom numbering system is shown. Estimated standard deviations are $2^{\circ}$ for all bond angles, except those at ring (ii) which are marked

(b)

Figure 2 The molecule viewed in directions (a) perpendicular to and (b) along the $\mathrm{B}-\mathrm{N}$ bond. The double circle in the centre of (b) represents a superposition of the three atoms $B, N$, and $C(31)$
pairs of mean planes listed in Table 4) are: $\mathrm{C}(18)-\mathrm{C}(13)-$ $\mathrm{B}-\mathrm{N}-51, \mathrm{C}(24)-\mathrm{C}(19)-\mathrm{B}-\mathrm{N}-65, \mathrm{C}(6)-\mathrm{C}(1)-\mathrm{C}(31)-\mathrm{N}$ $29^{\circ}$, and $\mathrm{C}(12)-\mathrm{C}(7)-\mathrm{C}(31)-\mathrm{N} 50^{\circ}$. The inequality of the torsion angles of the two mesityl groups (or the two phenyl groups), i.e. the failure of the molecule to possess a $C_{2}$ symmetry axis along the $\mathrm{B}-\mathrm{N}$ bond [see Figure 2(b)], must be the result of inter- rather than intra-molecular forces. The twist of the four benzene rings about the bonds joining them to $\mathrm{C}(31)$ or boron prevents them from having $\pi$-electron systems in common with the $\mathrm{C}(31)-\mathrm{N}$ or $\mathrm{B}-\mathrm{N}$ bonds.
length was calculated using the LCAO method as for other molecules examined in this series. ${ }^{1,12}$ Solution of the equations $\left[H_{k j}-E S_{k j}\right]\left[c_{j}\right]=0$ gave the eigenvalues $E_{1}$ and $E_{2}$ and the corresponding eigenvectors $\left[c_{j}\right]_{1}$ and $\left[c_{j}\right]_{2}$ (Table 5). The coulomb, overlap, and exchange integrals were derived as previously, ${ }^{1}$ with the values $S_{B N} 0.243$ and $H_{B N}-4.89 \mathrm{eV}$ corresponding to the bond

length $1.38 \AA$. With the two $\pi$-electrons occupying the bonding orbital $E_{2}$, the $\pi$-bond order $p_{\text {BN }}$ calculated from the eigenvectors taking into account overlap ${ }^{15}$ is 0.59 . The $\pi$-charge densities are $\rho_{N} 1.83$ and $\rho_{B} 0.17 \mathrm{e}$. The total boron-nitrogen bond order $(\sigma+\pi)$ is therefore 1.59 , which is slightly greater than that found ${ }^{12}$ for

Table 5

$\mathrm{Me}_{2} \mathrm{NBMe}_{2}(1 \cdot 57)$ reflecting the shorter bond length in $\mathrm{Ph}_{2} \mathrm{C}: \mathrm{NB}\left(\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Me}_{3}\right)_{2}$. This degree of $\pi$-bonding is considerably less than in ethylene and allene and is more comparable to that in benzene (bond order 1-67). An analogous LCAO calculation for the $\mathrm{C}=\mathrm{N}$ bond in $\mathrm{Ph}_{2} \mathrm{C}: \mathrm{NB}\left(\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Me}_{3}\right)_{2}$ gives $p_{\mathrm{ON}} 0 \cdot 84$, $\rho_{\mathrm{N}} 1 \cdot 56$, and $\rho_{\mathrm{C}}=$ 0.44 e . The $\mathrm{C}=\mathrm{N}$ length is similar to that in a number of oximes, e.g. p-chlorobenzaldoxime ( 1.26 and $1.27 \AA$ ). ${ }^{16}$

Other Bond Lengths and Bond Angles.-The mean B-C length $[1.59(2) \AA]$ is similar to the values usually found. ${ }^{14,17}$ The mean $\mathrm{C}-\mathrm{C}$ length in the benzene rings (i), (iii), and (iv) is $1 \cdot 390(6) \AA$. The bond lengths in ring (ii) cover a wide range and are clearly unreliable, in some cases having very large $\sigma$. The mean $\mathrm{C}($ ring $)-\mathrm{C}$ (methyl) length is $1 \cdot 52(1) \AA$.

The slight deviation of the $\mathrm{B}-\mathrm{N}-\mathrm{C}$ angle from $180^{\circ}$ results mainly from atom $\mathrm{C}(31)$ lying $0 \cdot 18 \AA$ away from the $\mathrm{C}(13)-\mathrm{C}(19)-\mathrm{B}-\mathrm{N}$ planar (Table 4$)$; the $\mathrm{B}-\mathrm{N}^{-} \mathrm{C}(31)$ plane is almost perpendicular to the $\mathrm{C}(13)-\mathrm{C}(19)-\mathrm{B}-\mathrm{N}$ plane (dihedral angle $87^{\circ}$ ).

Although the three bond angles at $\mathrm{C}(31)$ are equal within experimental error, those at the boron atom show a considerable departure from the ideal $120^{\circ}$. The $\mathrm{C}-\mathrm{B}-\mathrm{C}$ angle is probably enlarged in order to avoid interference between the mesityl groups, but even so some of the non-bonded contacts are very close, e.g. $\mathrm{C}(19) \cdots$ $\mathrm{C}(\mathbf{2 5}) 3 \cdot 19$ and $\mathrm{C}(13) \cdots \mathrm{C}(28) 3 \cdot 39 \AA$. Other bond angles are unexceptional.

The mesityl groups are planar, the deviations of the methyl carbon atoms from the mean plane of the ring being in all cases $<2 \cdot 3 \sigma$ (Table 4). Although phenyl ring (i) is planar and regular, ring (ii) is considerably distorted [Figure 1 (a) and Table 4] and has large thermal vibrations. The thermal parameters in Table 2 correspond to root-mean-square amplitudes of vibration up to $0.6 \AA$, whereas the atoms of ring (i) have root-meansquare amplitudes no larger than $0 \cdot 26 \AA$. The reason for the large (and very anisotropic) thermal vibrations of ring (ii) is probably that it lies in a region of the crystal lattice where the molecules are very loosely packed. The number of $\mathrm{C} \cdots \mathrm{C}$ intermolecular contacts

[^1]up to $4 \cdot 2 \AA$ made by the atoms of rings (i) and (ii) are as follows:

| $n$ | $\mathrm{C}(n)$ | $\mathrm{C}(6+n)$ |
| :---: | :---: | :---: |
| 1 | 3 | 1 |
| 2 | 3 | 1 |
| 3 | 7 | 3 |
| 4 | 9 | 4 |
| 5 | $12 *$ | 3 |
| 6 | 4 | 6 |

* One of the 12 contacts made by $C(5)$ is to a nitrogen atom.

With the exception of $\mathrm{C}(6)$ and $\mathrm{C}(12)$, each atom of ring (ii) makes considerably fewer contacts than the corresponding atom of ring (i). Moreover, whereas three atoms of ring (i) make contacts as short as $3.55-3.57 \AA$, no atom of ring (ii) has a contact $<3 \cdot 72 \AA$. The forces holding ring (ii) in place are clearly weaker than those holding ring (i). Such a disparity in environment does not occur between the two mesityl groups which show only minor differences in the number of contacts made by corresponding carbon atoms. The shortest inter-

molecular $\mathrm{CH}_{3} \cdots \mathrm{CH}_{3}$ contact is $3.82 \AA$ and the shortest $\mathrm{CH}_{3} \cdots \mathrm{CH}$ is $3 \cdot 80 \AA$.

A near-linear configuration has also been found for $\mathrm{Al} \leftarrow \mathrm{N}=\mathrm{C}$ (angle at nitrogen $167^{\circ}$ ) in $\mathrm{LiAl}\left(\mathrm{N}=\mathrm{CBu}_{2}^{\mathrm{t}}\right)_{4}{ }^{18}$ which again has a high-frequency azomethine stretching absorption ( $1700 \mathrm{~cm}^{-1}$ ). The wider implication of this and the present work is that allene-type geometries will apply to $\mathrm{M}-\mathrm{N}=\mathrm{CR}_{2}$ systems when M is an electron acceptor and a high azomethine stretching frequency is observed. Compounds satisfying these conditions are known for $\mathrm{M}=\mathrm{Be},{ }^{19} \mathrm{~B}, \mathrm{C},{ }^{8}$ and $\mathrm{Al} .^{20}$

I thank Drs. K. Wade and R. Snaith for supplying a sample of the aminoborane, the University of Essex Computing Centre and the Atlas Computer Laboratory, Chilton, for facilities, Dr. G. M. Sheldrick for making his computer programme available, $N$. Lewis for the preparation of diagrams, and the Department of Physical Chemistry, University of Cambridge, for its hospitality while this paper was being prepared.
