Metal Nitrido- and Oxo-complexes. Part I. Complexes of Ruthenium and Osmium

By William P. Griffith * and David Pawson. Department of Chemistry, Imperial College, London SW7 2AY

The preparation and physical properties of the new complexes $Cs_2[Ru(N)X_5]$ and $R[M(N)X_4]$ (M = Ru or Os; $R = Ph_4As$ or Bu^n_4N ; X = Cl or Br) are described. New binuclear nitrido-bridged complexes of ruthenium(IV) with carbonyl, cyanide, and chelate ligands, the polymeric nitrido-bridged species $[Os(N)BI_4]_n^{n-}$ and $[Os_3(N)_2X_{11}-(NH_3)_3]^{3-}$ (X = Cl or Br), and oxo- and dioxo-complexes of ruthenium are also reported. The structures of the species are discussed on the basis of vibrational spectra and other properties.

The nitride ion (N^{3-}) , like the isoelectronic oxide ion (O^{2-}) , can function as a terminal ligand ¹ or, less commonly, bridges two,² three,³ or four 4 metal atoms in linear, triangular, or tetrahedral arrays. Recently we briefly described the preparation of ruthenium(VI) terminal nitrido-salts $Cs_2[Ru(N)X_5]$ (X = Cl or Br) and related dioxo-species,⁵ and here we give fuller details of these and of other terminal nitrido-complexes. We also report an extension of our previous work on binuclear and polynuclear nitrido-bridged complexes of ruthenium and osmium.6

RESULTS AND DISCUSSION

Terminal Nitrido-complexes.-Mononuclear species containing M≡N groups have been established for very few metals, viz. vanadium,7 molybdenum and tungsten,8 rhenium,⁹ and osmium.¹⁰ In general the M \equiv N distance is short (*ca.* 1.7 Å), and the metal is in a high oxidation state due to the very effective σ - and π -donor properties of the nitrido-ligand.¹

Despite the considerable stability of nitrido-complexes of osmium(VI) and osmium(VIII), the only ruthenium nitrido-complexes hitherto established are binuclear with symmetric Ru-N-Ru units.⁶ We found that reaction of the complexes trans- $[Ru(O)_2X_4]^{2-}$ (X = Cl or Br) in ice-cold HX solution with an excess of azide ions

and caesium halide gave the light brown diamagnetic salts $Cs_2[Ru(N)X_5]$, and the known osmium complexes $Cs_2[Os(N)X_5]^{11}$ could be prepared by similar methods using trans- $[Os(O)_2X_4]^{2-}$. Liberation of free halogen and nitrogen during these reactions is consistent with the formation of a ruthenium(VI) or osmium(VI) azidocomplex which undergoes oxidative decomposition to the nitrido-complex. Furthermore, from the reaction of the complex trans- $[Os^{VI}(O)_2(OH)_4]^{2-}$ with azide and caesium ions in dilute acetic acid, the complex Cs[Os^{VIII}- $(O)_3N$ could be isolated (the 'osmiamate' ions do not react with acetic acid). Such a mechanism has been proposed for the formation of rhenium(v) nitrido-complexes from rhenium(III) species and azide ions,9 and of molybdenum(v1) nitrido-complexes from MoCl₅ and azide ions.12

The use of large organic cations as precipitants in place of caesium in the preparations of the $[M(N)X_5]^{2-}$ ions gave pink diamagnetic salts $R[M(N)X_4]$ (M = Ru or Os; $R = Ph_4As$ or Bu^n_4N ; X = Cl or Br), which were I: I electrolytes in acetone. It has been shown that the addition of $[Ph_4As]^+$ and $[Bun_4N]^+$ ions to solutions of $[{\rm Re}(N){\rm Cl}_{\tt J}]^{2-}$ precipitates $R[{\rm Re}(N){\rm Cl}_{\tt J}]^{,13}$ and mono-oxocomplexes $Cs_2[M(O)X_5]$, $R[M(O)X_4]$ (M = Mo or Re; $R = Ph_4As \text{ or } Bun_4N; X = Cl \text{ or } Br), and R[M(O)X_4L]$ (L = solvent molecule) can be isolated.^{14,15} The considerable repulsion between the axial π -donor and the equatorial halide ligands in $[M(N)X_5]^{2-}$ or

 $[M(O)X_4L]^-$ tends to weaken the *trans*-axial ligand ¹⁶ as shown by X-ray studies of the complexes $K_2[Os(N)Cl_5]$,¹⁶ trans-[Re(O)Br₄L]⁻ (L = MeCN or H₂O),^{$\overline{14}$} [Re(O)Cl₄- (H_2O)],¹⁷ and [Ph₄As][Mo(O)Br₄(H₂O)].¹⁸ Lattice-energy considerations may also be important.

Vibrational spectra. The main features and assignments of the vibrational spectra of the terminal nitridocomplexes are summarised in the Table. We find that the M=N stretching frequency v_{MN} is higher for the solid salts $R[M(N)X_4]$ and $[Os(N)X_5]^{2-}$ than for the corresponding $Cs_2[M(N)X_5]$ species (M = Ru or Os; $X = Cl \text{ or } Br; \ \bar{R} = Ph_4As \text{ or } Bun_4N).$ This may be due to interaction between the polarisable Cs⁺ ion and

plexes are some 10% higher than those in the corresponding $Cs_2[M(N)X_5]$ salts. This remarkable increase may be due to the four halide ligands in solid $R[M(N)X_4]$ adopting a position which gives better σ - and π -overlap with the appropriate metal orbitals, steric constraints imposed by the sixth trans-ligand being removed. Such an effect has been observed in X-ray studies of the complexes trans-[Re(O)Cl₄(H₂O)]¹⁷ and monomeric [Re- $(O)Cl_{4}$; ²² in the latter the Cl-Re-O angle of 105° is some 7° greater than in the former, and the Re-Cl distance is shorter.

Binuclear Nitrido-complexes.—The anion in K₃[Ru₂- $(N)Cl_8(H_2O)_2$ is centrosymmetric $(D_{4h}$ with a linear

Bands due to the cation are not quoted. All spectra from i.r. studies on solids, except where indicated. Frequencies in parentheses refer to ¹⁵N substituted species.

* Raman data on the solid. † Spectra on complex in D₂O solution with an excess of the X-ion. ‡ In D₂O solution.

the nitrido-ligand; an analogous effect has been noted for rhenium(v) oxo-species.¹⁴ This frequency is also higher for osmium than those for ruthenium in corresponding complexes and the stretching force constant $k_{\rm MN}$ has been shown to be some 10% higher for osmium than that for ruthenium.¹⁹ The $X - M \equiv N$ bending mode has been identified for the first time in nitrido-complexes by ¹⁵N substitution; it is ca. 250 cm⁻¹ and changes in sympathy with v_{MN} .

The spectra of the $R[M(N)X_4]$ salts are consistent with the C_{4v} symmetry of the square-based pyramid.* The presence of substantial \cdots M=N \cdots M=N \cdots linear chain bonding seems unlikely; it has been shown that the complexes $K_{2n}[Re(N)(CN)_4]_n^{20}$ and $[W(O)Cl_4]_n^{21}$ contain such chains and their i.r. spectra in the 850-1100 cm^{-1} region, as compared with those of $K_3[Re(N)(CN)_5]$ and monomeric $[W(O)Cl_4]$ respectively, show a lowering and considerable broadening of the stretching modes. No such effect is observed with the $R[M(N)X_4]$ salts as compared with those of $Cs_2[M(N)X_5]$.

The M-X stretching modes in the $R[M(N)X_4]$ com-

Note added in proof: Single-crystal X-ray studies on the salt $[Ph_4As][OsNCl_4]$ confirm that the anion has $C_{4\nu}$ symmetry (F. Phillips and A. C. Skapski, unpublished work).

Ru-N-Ru unit).^{2,6} Here we describe complexes containing such a Ru-N-Ru unit with ligands not normally found with ruthenium(IV).

Solutions of the complex $K_3[Ru_2(N)Cl_8(H_2O)_2]$, when heated under reflux in concentrated aqueous HX (X =Cl or Br), slowly take up carbon monoxide, and from the resulting solutions the complexes Cs₃[Ru₂(N)X₈(CO)₂] could be obtained. The reaction only occurs in strong acid; analogous reactions are found for solutions of [RuCl₆]³⁻ in HCl.²³ It is also possible to obtain chlorocarbonyl species by reaction of the complex K₃[Ru₂(N)- $Cl_8(H_2O)_2$ in formic acid-hydrochloric acid (2:1) (again, [RuCl₆]³⁻ undergoes an analogous reaction with HCO₂H-HCl).²³ Although we were unable to obtain the Raman spectra of the Cs₃[Ru₂(N)X₈(CO)₂] complexes because of their colours, the i.r. spectra in the metalhalogen stretching regions are very similar in profile to those of the complexes K₃[Ru₂(N)X₈(H₂O)₂], which suggests that the carbonyl groups are trans to the

nitrido-group as are the water ligands in the parent species. The asymmetric Ru₂N stretching frequency of the carbonyl complexes is some 40 cm⁻¹ lower than those of the corresponding aquo-species; if the carbonyl groups are indeed trans to the nitrido-group, this drop in frequency may well arise from competition of CO and N^{3-} ligands for the same metal t_{2g} orbitals. A related situation is that in the complex trans-[Ru^{II}(NO)(NH₂)- $(NH_3)_4]^{2+}$, where the terminal π -donor amide ligand is stabilised by the strongly π -accepting nitrosyl group.²⁴

The reaction of $[Ru_2(N)Cl_8(H_2O)_2]^{3-}$ with potassium cyanide gave the very stable species $K_5[Ru_2(N)(CN)_{10}]$,-3H₂O. The i.r. spectrum of the solid was very complex in the C=N stretching region and also showed sharp highfrequency water bands; on dehydration the $C\equiv N$ band structure became much simpler. This behaviour is similar to that observed for the complex Na₂[Fe(CN)₅-NO, 2H₂O, where X-ray and careful i.r. studies have shown that the water molecules occupy equivalent sites in the lattice and have low site symmetry with very weak hydrogen bonding.²⁵ The nitrido-species is stable in aqueous solution and there is no evidence that aquation occurs. The Raman spectrum of the dehydrated solid was similar to that of the solution, suggesting that there is no change of configuration in the latter. In solution we observed four Raman modes (two polarised, one an intense band at 2156 cm⁻¹, and a weaker band at 2116 cm⁻¹) and three i.r. bands with no coincidences between the two sets. However, for both the probable symmetries D_{4h} (equatorial ligands eclipsed), as found in $K_3[Ru_2(N)Cl_8(H_2O)_2]$,² and D_{4d} (equatorial ligands staggered), as in $[Mn_2(CO)_{10}]$,²⁶ we expect this behaviour. Although no distinction can be drawn between these two symmetries on the basis of our study, the difference in band profiles in the 2000 cm⁻¹ region for [Ru₂(N)- $(CN)_{10}$ ⁵⁻ compared with $[Mn_2(CO)_{10}]$ and $[Co_2(CN)_{10}]$ ⁶⁻ (ref. 26) suggests that the complex has the expected D_{4h} symmetry in solution. We provisionally assign the strongest polarised band to the symmetric stretch of the cyano-ligands, and the weaker band to that of the axial ligands. The symmetric Ru₂N stretch occurs as a strong, polarised band at 264 cm⁻¹ in the Raman spectrum of the solution.

The existence of carbonyl and cyano-complexes of ruthenium(IV) is unusual; it appears that ruthenium in these binuclear species is behaving more as ruthenium(III) or even ruthenium(II). This is probably due to the strong π -donor effect of the nitrido-ligand which, in effect, fills the t_{2g} orbitals of each metal atom which then behaves as a pseudo- d^6 system, ready to delocalise electron density on to π -acceptor ligands. There is also evidence for the formation of phosphine and nitrosyl complexes containing the Ru₂N system.

Despite the steric constraints imposed by the short ruthenium-nitrido-group bonds {Ru-N = 1.718 Å in $K_3[Ru_2(N)Cl_8(H_2O)_2]^2$, it is possible to isolate stable complexes containing the Ru₂N system with chelating ligands, e.g. $[Ru_2(N)(dae)_4Cl_2]Cl_3$ and $[Ru_2(N)(bipy)_4Cl_2]$ - $(PF_6)_3$ (dae = 1,2-diaminoethane, bipy = 2,2'-bipyridine); in the latter case the 2,2'-bipyridine ligands are presumably not in a plane about each ruthenium atom ²⁷ so that the chloro-ligands are likely to be cis to the nitrido-ligand. A diethyldithiocarbamate complex, $[Ru_2(N)(S_2CNEt_2)_4Cl]$ has also been prepared; this is a non-electrolyte in acetone solution and may be polymeric in the solid state with ··· Ru-Cl-Ru-N-Ru-Cl··· chains.

Polynuclear Nitrido-complexes of Osmium.-Dehydration of the red salt $K[Os(N)Br_4(H_2O)], H_2O$ at 110 °C gave a green substance, $K_n[Os(N)Br_4]_n$, which quickly reverted to the starting material on setting aside in the atmosphere. Comparison of the i.r. spectra of K[Os(N)Br₄(H₂O)],H₂O and $K_n[Os(N)Br_4]_n$ shows that, whereas the Os=N stretching frequency in the former is sharp and intense at 1109 cm⁻¹, in the latter it is much broader and drops to 1002 cm⁻¹; the N≡Os-Br bending mode drops below 200 cm⁻¹. We propose that in this complex $\tilde{K}_n[Os(N)Br_4]_n$, as in that of $K_{2n}[Re(N)(CN)_4]_n$,²⁰ there are linear \cdots M \equiv N \cdots M \equiv N \cdots chains.

The reaction of osmium tetraoxide with concentrated aqueous ammonia yields a black, diamagnetic material originally formulated as [OsO₂(NH₃)₂(H₂O)]; with hydrochloric acid, $[OsCl_4(NH_3)_2]$ is said to be formed.²⁸ We found that, from solutions of the black material in HX, the caesium salts $Cs_3[Os_3(N)_2X_{11}(NH_3)_3], 2H_2O$ (X = Cl or Br) could be precipitated; the salts are brown and diamagnetic. The i.r. spectra of the normal and deuteriated salts showed bands due to co-ordinated NH_3 or ND_3 ; two strong bands in the 950-1100 cm⁻¹ region were, however, barely shifted by deuteriation, and these we assign to bridging nitrido-ligands. We propose that these complexes have the structure (I)

and the diamagnetism of this formally Os^v-Os^{iv}-Os^v species may then be rationalised using the bonding scheme applied to ruthenium red, $[Ru_3(O)_2(NH_3)_{14}]^{6+,29}$ which has an analogous structure.³⁰ A similar structural unit has been proposed for the product obtained from the prolonged reaction of osmium tetraoxide and liquid ammonia.^{6,31}

Ruthenium Oxo-complexes.—The formation of [Ru- $(N)Cl_5$ ²⁻ from azide and trans-[Ru(O)₂Cl₄]²⁻ ions prompted a further investigation of ruthenium oxo-complexes as possible precursors for nitrido-species. Only trans- $[Ru(O)_2Br_4]^{2-}$ ions were useful in this respect, but we have isolated a number of other oxo-species in the course of this work. The only firmly established 'ruthenyl' species are those of $trans-Cs_2[Ru(O)_2Cl_4]^{32}$ and $trans-[Ru(O)_2(OH)_2(py)_2]$ (py = pyridine); ³³ although spectroscopic data have been reported on salts of the anions $[Ru(O)_2Br_4]^{2-}$ and $[Ru(O)_2(SO_4)_2]^{2-}$, no preparative details were given.³⁴

From solutions of ruthenium tetraoxide in carbon tetrachloride with ice-cold solutions of HX and CsX $(X = Br \text{ or } \frac{1}{2}C_2O_4)$, the salts $Cs_2[Ru(O)_2X_4]$ were obtained; from mildly alkaline solutions of RCl ($R = NH_4$, Hbipy, or Hpy), the species $[Ru(O)_2(NH_3)_4]Cl_2$, $[Ru(O)_2(bipy) Cl_2$], and $[Ru(O)_2(py)_2Cl_2]$ were similarly obtained. All the complexes are diamagnetic, consistent with there being a trans-RuO₂ unit, as in the corresponding osmium dioxo-species.³⁵ The complexes all showed a characteristic strong band in the i.r. ca. 830 cm⁻¹ which we assign to the asymmetric RuO₂ stretch, while for those complexes whose Raman spectra could be measured the symmetric RuO₂ stretch appeared in the same region. The stretching force constants for the RuO₂ systems, calculated from the equations of Cotton and Wing,³⁶ are some 10% lower than those for the corresponding osmium species.37

The reaction of ruthenium tetraoxide with an ice-cold solution of sodium cyanide in the presence of caesium ion did not, surprisingly, yield the complex $Cs_2[Ru(O)_2]$ - $(CN)_{4}$; a green paramagnetic salt, which showed i.r. bands characteristic of co-ordinated cyano- and isocyanato-groups, was formed. We formulate this complex as Cs₃[Ru(O)(CN)₄(CNO)₂]; a strong band at 787 cm^{-1} in the i.r. spectrum, which also appeared in the Raman spectrum of the solid, is assigned to the Ru=O stretch. The magnetic moment of 3.0 B.M. is similar to that recently reported for arylimido-complexes of osmium(v).³⁸ The reaction of potassium tetraoxoruthenate(VI) with sodium cyanide in the presence of caesium ions yielded a yellow paramagnetic material $Cs_5[Ru_2(O)_5(CN)_9]$, the structure of which is still under investigation.

EXPERIMENTAL

Dicaesium Pentachloronitridoruthenate(VI), Cs₂[Ru(N)Cl₅]. -A solution of ruthenium tetraoxide in carbon tetrachloride (10 cm³) (vide infra) was stirred rapidly with 8Mhydrochloric acid (7 cm³), and the resulting red solution cooled to 0 °C. Sodium azide (0.24 g) was added to the reaction mixture and the solution stirred at room temperature until effervescence had ceased (ca. 15 min). Caesium chloride (0.8 g) was added and the light brown *precipitate* (80%) was filtered off, washed with ice-cold concentrated

hydrochloric acid (2 cm³), then acetone, and finally dried at 110 °C [Found: Cl, 31·4; Cs, 47·5; N, 2·6. Cl₅Cs₂NRu requires Cl, 31.8; Cs, 47.6; N, 2.5%].

Tetrachloronitridoruthenate(VI), **Tetraphenylarsonium** [Ph₄As][Ru(N)Cl₄].—A solution of tetraphenylarsonium chloride (0.8 g) in methanol (5 cm^3) was added to the above reaction mixture in the place of caesium chloride. The pink precipitate (80%) which formed was filtered off, washed with water and methanol, and recrystallised from acetonitrile [Found: C, 45.0; H, 3.2; Cl, 22.9; N, 2.1. C₂₄H₂₀-AsCl₄NRu requires C, 45.0; H, 3.1; Cl, 22.2; N, 2.2%].

Tetra-n-butylammonium Tetrachloronitridoruthenate(VI), $[Bu^n_4N][Ru(N)Cl_4].--Tetra-n-butylammonium \quad hydroxide$ solution $(40\%, 2 \text{ cm}^3)$ replaced tetraphenylarsonium chloride solution in the preceding preparation. The pale pink precipitate (80%) which formed was filtered off, washed with water and diethyl ether, and recrystallised from acetone to give brown crystals of the product [Found: C, 38·4; H, 7·0; Cl, 28·9; N, 5·2. C₁₆H₃₆Cl₄N₂Ru requires C, 38.5; H, 7.2; Cl, 28.4; N, 5.6%]. I.r. spectrum (excluding cation bands): 1095m; 376s; and 265m cm⁻¹. Molar conductance (in acetone) 121 Ω^{-1} cm⁻² in 10⁻³Msolution.

Dicaesium Pentabromonitridoruthenate(VI), $Cs_2[Ru(N)Br_5]$. ---Sodium azide (0.24 g) was dissolved in an ice-cold solution of water (2 cm³) and concentrated hydrobromic acid (5 cm³). Ruthenium tetraoxide solution (10 cm³, vide infra) was added to the solution and the mixture stirred vigorously at $0 \,^{\circ}C$ (5 min). Caesium bromide (0.9 g) was added to the solution and the light brown product (40%) was filtered off, washed with acetone, and dried at 110 °C [Found: Br, 50.3; Cs, 34.2; N, 1.9. Br₅Cs₂NRu requires Br, 51.2; Cs, 34.1; N, 1.8%].

Tetraphenylarsonium Tetrabromonitridoruthenate(VI) [Ph4-As][RuNBr₄].—A solution of tetraphenylarsonium chloride (0.5 g) in methanol (5 cm^3) was added to the above reaction mixture in the place of caesium bromide. The bulky yellow precipitate which formed was filtered off and washed with methanol to leave a light pink precipitate (40%) [Found: C, 35·2; H, 2·6; Br, 38·9; N, 1·6. C₂₄H₂₀AsBr₄NRu requires C, 35.2; H, 2.4; Br, 39.1; N, 1.7%].

Dicaesium Pentahalogenonitrido-osmate(VI), Cs₂[Os(N)X₅] (X = Cl or Br).—The chloro- and bromo-complexes were prepared by literature methods;¹¹ an alternative procedure which eliminates contamination with the corresponding osmium(VI) dioxo-complex is as follows.

Chloro-complex.-Potassium osmate (0.08 g) was dissolved in concentrated hydrochloric acid (3 cm³) and sodium azide solution $(0.03 \text{ g in } 1 \text{ cm}^3 \text{ water})$ added. The solution was stirred (20 min) and caesium chloride (0.05 g) was added to precipitate the purple product.

Bromo-complex. The procedure was similar to that used for the chloro-complex but hydrobromic acid and caesium bromide were used to give the purple product.

Organic cation salts of the tetrahalogeno-osmate(vi) complexes were precipitated from solutions of $[Os(N)X_5]^{2-}$ in HX (X = Cl or Br) using the procedures described for the ruthenium salts. Tetraphenylarsonium tetrachloronitridoosmate(vi), $[Ph_4As][Os(N)Cl_4]$. Pink crystals (90%) [Found : C, 39.5; H, 2.9; Cl, 19.2; N, 2.0. C₂₄H₂₀AsCl₄NOs requires

Deep red crystals (90%) [Found: Br, 40.8; N, 3.5. C₁₆H₃₆Br₄N₂Os requires Br, 41.7; N, 3.7%]. I.r. bands (excluding cation absorptions): 1120m; 270s; and 232m cm⁻¹. Molar conductance (in acetone) 124 Ω^{-1} cm⁻² in 10⁻³M-solution.

Tricaesium Dicarbonyloctachloro- μ -nitrido-diruthenate(IV), Cs₃[Ru₂(N)Cl₃(CO)₂].—Method (a). The complex K₃[Ru₂-(N)Cl₃(H₂O)₂] (2·5 g) was heated under reflux in concentrated hydrochloric acid (25 cm³) under a stream of carbon monoxide (15 h). The solution was cooled, hydrochloric acid (10 cm³) added, and the resulting solution set aside under the gas stream (1 h). The solution was then filtered to remove starting material, and caesium chloride (2·0 g) added to precipitate the light brown product (30%), which was filtered off and washed with acetone [Found: C, 1·9; Cl, 30·3; Cs, 41·2; N, 1·3. C₂Cl₈Cs₃NO₂Ru₂ requires C, 2·5; Cl, 29·7; Cs, 41·7; N, 1·5%].

Method (b). The complex $K_3[Ru_2(N)Cl_8(H_2O)_2]$ (2.0 g) was dissolved in boiling water and the insoluble precipitate $Ru_2(N)(OH)_5, nH_2O$ formed by the addition of sodium hydroxide. The precipitate was filtered off, washed with boiling water, and dissolved in formic acid-hydrochloric acid (2:1, 20 cm³). The resulting solution was heated under reflux (90 min) and on cooling caesium chloride (2.0 g) was added to give a yellow-brown precipitate, which was mainly the caesium salt of the starting material. The precipitate was filtered off and acetone (50 cm³) added to the filtrate to precipitate the light brown product (10%); the latter was filtered off and washed with acetone [Found: C, 2.0; Cl, 30.1; Cs, 42.1; N, 1.5%]. I.r. spectrum: 2038s; 1016s; 590w; 520w; 470m; 321s; 300m; and 264m cm⁻¹.

Tricaesium Octabromodicarbonyl- μ -nitrido-diruthenate(IV), Cs₃[Ru₂(N)Br₈(CO)₂].—An adaption of method (a) for the chloro-complex was used, with K₃[Ru₂(N)Br₈(H₂O)₂], hydrobromic acid, caesium bromide, and a reflux time of 6 h. The complex is yellow-brown [Found: C, 1·7; Br, 49·3; Cs, 31·2; N, 1·3. C₂Br₈Cs₃NO₂Ru₂ requires C, 1·8; Br, 48·5; Cs, 30·4; N, 1·1%]. I.r. spectrum: 2022s; 1970m; 984s; 570w; 538w; 500w; 457m; 432w; 245s; and 210m cm⁻¹.

Potassium Decacyano- μ -nitrido-diruthenate(IV), K₅[Ru₂-(N)(CN)₁₀], 3H₂O.—The complex K₃[Ru₂(N)Cl₈(H₂O)₂] (1.0 g) was dissolved in boiling water and the insoluble precipitate Ru₂(N)(OH)₅, nH₂O formed by the addition of sodium hydroxide. The precipitate was washed with boiling water and stirred (20 min) in a boiling aqueous solution of potassium cyanide (4 g in 10 cm³). The cooled yellow solution was poured into methanol (40 cm³) and the yellow precipitate (80%) which formed was filtered off and washed with boiling methanol (200 cm³) [Found (for the trihydrate): C, 16·3; K, 26·7; N, 20·9. C₁₀H₆K₅N₁₁O₃Ru₂ requires C, 16·5; K, 26·9; N, 21·2%]. I.r.: (dehydrated solid) 2150m; 2140s; 2138ssh; 2120s; 2088m; 2078m; 2055m; 2040m,

Dichlorotetrakis(1,2-diaminoethane)- μ -nitrido-diruthenium-(IV) Trichloride, [Ru₂(N)(dae)₄Cl₂]Cl₃.—A solution of the complex K₃[Ru₂(N)Cl₈(H₂O)₂] (1 g) in boiling water (10 cm³) was added to boiling aqueous 1,2-diaminoethane (50%, 20 cm³) and the solution heated under reflux (3 h). Hydrochloric acid (2 cm³) was added to the cooled orange solution to precipitate orange crystals of the complex [Found: C, 14·9; H, 5·3; Cl, 27·2; N, 19·7. C₈H₃₂Cl₅-N₉Ru₂ requires C, 15·2; H, 5·1; Cl, 28·0; N, 19·9%]. I.r. spectrum (neglecting bands due to 1,2-diaminoethane): 1052s and 315m cm⁻¹. Raman spectrum; 359(6); 353(5); 260(7); 202(3); and 174(1) cm⁻¹.

(aqueous solution) 2156(7); † 2142(6); 2130(3); 2116(1); †

Chlorotetrakis(diethyldithiocarbamato)- μ -nitrido-diruthenium(IV), [Ru₂(N)(S₂CNEt₂)₄Cl]. Hot solutions of the complex K₃[Ru₂(N)Cl₈(H₂O)₂] (1·0 g in 10 cm³ water) and sodium diethyldithiocarbamate (4·0 g in 10 cm³ water) were mixed and warmed on a steam-bath (2 min). The brown precipitate which formed was filtered off and dissolved in acetone. This solution was filtered and evaporated to dryness to give the brown product (60%) [Found: C, 29·6; H, 4·9; Cl, 3·3; N, 8·6; S, 30·2. C₂₀H₄₀ClN₅Ru₂S₈ requires C, 28·4; H, 4·7; Cl, 4·2; N, 8·3; S, 30·3%]. ν_{M_5N} (asym) 1030 cm⁻¹.

Potassium catena- μ -Nitrido-tetrabromo-osmate(VI), K_n [Os-(N)Br₄]_n.—A sample of the complex K[Os(N)Br₄(H₂O)],-H₂O, prepared by a literature method,¹¹ was heated to 110 °C (15 min) and the green *product* sealed in an ampoule [Found: Br, 56·7. Br₄KNOs requires Br, 56·8%]. Weight loss on dehydration: 6·5. Calc. for 2H₂O: 6·0%.

Tricaesium Di-µ-nitrido-bis[amminetetrachloro-osmate(v)]-[amminetrichloro-osmate(IV)] Dihydrate, $Cs_3[Os_3(N)_2Cl_{11}-$ (NH₃)₃],2H₂O.—The method of Claus ²⁸ was used to prepare the complex $[Os(O)_2(NH_3)_2H_2O]$ which we reformulate $[Os_3(N)_2(OH)_8(NH_3)_3], H_2O.$ The black complex (1.0 g) was heated under reflux in concentrated hydrochloric acid (30 min) and the solution then filtered. To the filtrate was added caesium chloride (2.0 g) to precipitate the brown product (40%). The latter was filtered off, washed with concentrated hydrochloric acid and acetone, and dried at 110 °C [Found: Cl, 26.7; Cs, 26.0; N, 5.2. C₁₁H₁₃Cs₃-N₅O₂Os₃ requires Cl, 26.4; Cs, 27.0; N, 4.8%]. I.r. spectrum (figures in parentheses refer to deuteriated sample): 3540sb (2430); 3260s (2300); 3200s (2260); 1620s (1225); 1565msh (1140); 1335s(obsc.); 1025ms; 970s; 550m; 450m; and 320s cm⁻¹.

† Band polarised.

Tricaesium Di- μ -nitrido-bis[amminetetrabromo-osmate(v)]-[amminetribromo-osmate(IV)] Dihydrate, Cs₃[Os₃(N)₂Br₁₁-(NH₃)₃],2H₂O.—The method used was similar to that used from the chloro-complex except that hydrobromic acid and caesium bromide (40%) were employed [Found: Br, 44·8; Cs, 19·3; N, 4·4. H₁₃Br₁₁Cs₃N₅O₂Os₃ requires Br, 44·8; Cs, 20·3; N, 3·6%]. I.r. spectrum: 3510sb; 3200s; 3120s; 1610s; 1550msh; 1322m; 1115w; 1015ms; 957s; and 230s cm⁻¹.

Dicaesium trans-Tetrabromodioxoruthenate(VI), $Cs_2[Ru(O)_2-Br_4]$.—A saturated solution of caesium bromide in hydrobromic acid (5 cm³) and water (2 cm³) was cooled to 0 °C and ice-cool ruthenium tetraoxide solution (5 cm³) was stirred into it. The light brown *precipitate* (40%) which formed was quickly filtered off, sucked dry on a frit, and washed with acetone [Found: Br, 43.9; Cs, 37.6. Br₄Cs₂-O₂Ru requires Br, 44.5; Cs, 37.0%]. I.r. spectrum: 825s; * 821ssh; * 230s; and 226ssh cm⁻¹.

Dicaesium trans-Bisoxalatodioxoruthenate(VI), $Cs_2[Ru(O)_2-(ox)_2]$.—Oxalic acid (0.45 g) and caesium carbonate dihydrate (0.90 g) were dissolved in water (4 cm³) and the solution cooled in ice. Ruthenium tetraoxide solution (6 cm³) was stirred into this solution and the light green precipitate (30%) which formed was filtered off after 5 min, and washed with carbon tetrachloride and ethanol [Found: C, 8.0; Cs, 45.8. C₄Cs₂O₁₀Ru requires C, 8.4; Cs, 46.2%]. I.r. spectrum: 1710sb; 1680s; 1668s; 1335s; 1192m; 910w; 878m; 838s; * 810s; 549m; 460m; 385w; 361ssh; and 350s cm⁻¹.

trans-Tetra-amminedioxoruthenium(VI) Dichloride, [Ru-(O)₂(NH₃)₄]Cl₂.—Ammonium chloride (1.0 g) and sodium carbonate (0.1 g) were dissolved in ice-cold water (4 cm³) and ruthenium tetraoxide solution (6 cm³) was stirred into the resulting mixture. After 15 min the yellow microcrystalline precipitate was filtered off and washed with carbon tetrachloride and ethanol [Found: H, 4.7; Cl, 26.4; N, 20.7; O, 12.1. H₁₂Cl₂N₄O₂Ru requires H, 4.4; Cl, 26.1; N, 20.6; O, 11.8%]. I.r. spectrum (deuteriated sample in parentheses): 3360vsb (2420); 3070vsb (2280); 1660m; 1623m (1148); 1583m; 1540msh (1080); 1322s (1018); 1304s (1008); 870s (650); 845s; * 782s (622); 478m (440); 278sb (250); and 215s cm⁻¹. Raman spectrum: 841 (10) cm⁻¹.

trans-Dichlorodioxodipyridineruthenium(v1), [Ru(O)₂(py)₂-Cl₂].—A solution of pyridine (1 cm³) in water (2 cm³) was neutralised with hydrochloric acid and the solution made alkaline with sodium carbonate (0·1 g). Ruthenium tetraoxide solution (6 cm³) was stirred into the ice-cool solution and, after 5 min, the yellow microcrystalline *product* was filtered off and washed with carbon tetrachloride, water, and ethanol [Found: C, 34·0; H, 2·9; Cl, 18·8; N, 7·9. C₁₀H₁₀Cl₂N₂O₂Ru requires C, 33·1; H, 2·8; Cl, 19·6; N, 7·7%]. I.r. spectrum (neglecting bands due to pyridine): 825s * and 325 cm⁻¹. trans-(2,2'-Bipyridine) dichlorodioxoruthenium(VI), [Ru(O)₂-(bipy)Cl₂].—2,2'-Bipyridine (0·3 g) was stirred into water (3 cm³) and 2M-hydrochloric acid added until the ligand was completely dissolved. Sodium carbonate (0·1 g) was added to the ice-cool solution, and then ruthenium tetra-oxide solution (6 cm³). The yellow crystalline *product* was filtered off after 5 min and washed with water and acetone [Found: C, 33·6; H, 2·4; Cl, 19·6; N, 7·9. C₁₀H₈Cl₂N₂O₂-Ru requires C, 33·3; H, 2·2; Cl, 19·7; N, 7·8%]. I.r. spectrum: 839s; * 325s; and 319ssh cm⁻¹.

Tricaesium Tetracyanodi-isocyanato-oxoruthenate(v), Cs₃-[Ru(O)(CN)₄(CNO)₂].—Ruthenium tetraoxide solution (5 cm³) was stirred with an ice-cold saturated aqueous solution of sodium cyanide (5 cm³) which contained caesium chloride (1·09 g). The green precipitate which formed was filtered off after 5 min and washed with methanol [Found: C, 10·2; Cs, 56·7; N, 12·3; O, 6·7. C₆Cs₃N₆O₃Ru requires C, 10·2; Cs, 56·4; N, 11·9; O, 6·8%]. I.r. spectrum: 3600w; 3315w; 3440w; 2195vs; 2125s; 2060w; 1630w; 1335w; 787s; 690w; 640w; 609w; 450w; 388ms; 370ms; and 328m cm⁻¹. Raman spectrum: 2200(1); 2149(5); and 787(10) cm⁻¹. χ g 5·57 × 10⁻⁶ c.g.s.u., $\mu_{eff} = 3\cdot00$ B.M.

Ruthenium Tetraoxide Solution.—The solution of ruthenium tetraoxide in carbon tetrachloride was prepared by an adaptation of Nakata's method,³⁹ commercial ruthenium trichloride (10 g) being converted to the hydrated hydroxide which was then oxidised by sodium periodate (45 g in 400 cm³ ice-cold water). The resulting aqueous solution of RuO₄ was divided into three portions and each portion was extracted with 3×30 cm³ of carbon tetrachloride, the final solution being made up to 300 cm³ to give a ruthenium tetraoxide concentration of *ca*. 22 g l⁻¹. The solution was stored at -5 °C in the presence of sodium periodate.

All the complexes are diamagnetic unless otherwise stated. The complex $K_2[Os(N)Cl_5]$ was prepared by the literature method.¹¹ The ¹⁵N substituted osmium complexes were prepared from $K[Os(O)_3^{15}N]$ obtained from isotopically enriched ammonium chloride (95%) and osmium tetraoxide in potassium hydroxide solution. I.r. spectra were measured as Nujol mulls between caesium iodide plates on a Perkin-Elmer 325 instrument (4000—200 cm⁻¹) and Raman spectra (1200—140 cm⁻¹) on a Cary 81 instrument with a CRL52 Kr laser using excitation at 6471, 5682, and 5308 Å. Microanalyses were performed by the Microanalytical Department at Imperial College and Alfred Bernhardt, Munich; caesium and potassium were determined as the tetraphenylborates.

We thank Johnson, Matthey for the loan of platinum metal compounds, and the S.R.C. and Johnson, Matthey for a C.A.P.S. award (to D. P.).
