## Distorted Dodecahedral Co-ordination in the Crystal Structure of Isoquinolinium Tetrakis[4,4,4-trifluoro-1-(2-thienyl)butane-1,3-dionato]cerium(III)

By Andrew T. McPhail " and Pui-Suen Wong Tschang, Paul M. Gross Chemical Laboratory, Duke University, Durham, North Carolina 27706, U.S.A.

The crystal structure of isoquinolinium tetrakis[4.4.4-trifluoro-1-(2-thienyl)butane-1,3-dionato]cerium (III) has been established by three-dimensional $X$-ray analysis and the molecular parameters refined by full-matrix leastsquares calculations to $R 0.128$ over 5325 observed reflections from photographic data. The crystals are monoclinic, space group $P 2_{1} / c, a=22 \cdot 76(4), b=10 \cdot 85(2), c=20 \cdot 13(4) A, \beta=112 \cdot 58(10)^{\circ}, Z=4$. Eight oxygen atoms surround the cerium atom, mean $\mathrm{Ce}-\mathrm{O}=2.470 \AA$, in a dodecahedral arrangement distorted by an $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond from the isoquinolinium ion.

Eight-co-ordinate metal complexes of the type $\mathrm{MX}_{4}$, where $\mathrm{X}=$ bidentate ligand, occur predominantly with either square antiprismatic ( $\overline{8} 2 m-D_{4 d}$ ) or dodecahedral $\left(\overline{4} 2 m-D_{2 d}\right.$ ) stereochemistry. ${ }^{1-3}$ The small potential energy difference between these two favoured forms makes it difficult to predict which geometry will be preferred in a particular complex ${ }^{4}$ and intermediate forms are sometimes found. Previous structural studies on

anionic complexes of trivalent lanthanoids, $M(\beta$-diketone) ${ }_{4}{ }^{-}$, have involved either spherically symmetric $\mathrm{Cs}^{+}$cations or the $\mathrm{NH}_{4}{ }^{+}$ion, neither of which would be expected to perturb significantly the co-ordination geometry around the lanthanoid ion. In contrast, the presence of a lower symmetry counterion which has the

potential to associate with the atoms in the co-ordination polyhedron might be expected further to complicate the situation. Accordingly, we have elucidated the crystal structure of the isoquinolinium salt of tetrakis $[4,4,4-$ trifluoro-1-(2-thienyl) butane-1,3-dionato]cerium(III),
$\left[\mathrm{Ce}(\mathrm{ttb})_{4}\right]^{-}$, in order to define the geometry around the cerium(III) ion.

## EXPERIMENTAL

Crystal Data. $-\mathrm{C}_{41} \mathrm{H}_{24} \mathrm{CeF}_{12} \mathrm{NO}_{8} \mathrm{~S}_{4}, \quad M=1155$, Monoclinic, $\quad a=22 \cdot 76(4), \quad b=10 \cdot 85(2), \quad c=20 \cdot 13(4) \quad \AA, \quad \beta=$ $112.58(10)^{\circ}, U=4590 \AA^{3} ; D_{\mathrm{m}}=1 \cdot 66, Z=4, D_{\mathrm{c}}=1.676$, $F(000)=2284, \mu\left(\mathrm{Cu}-K_{\alpha}, \lambda=1.542 \AA\right)=99 \mathrm{~cm}^{-1}$. Space group $P 2_{1} / c\left(C_{2 h}^{5}\right)$ from absent spectra, $0 k 0$ when $k \neq 2 n$, hol when $l \neq 2 n$.

Crystallographic Measurements.-Unit cell dimensions were obtained from zero-level Weissenberg photographs taken with $\mathrm{Cu}-K_{\alpha}$ radiation and precession photographs taken with Mo- $K_{\alpha}(\lambda=0.7107 \AA)$ radiation. Threedimensional intensity data were estimated visually from equi-inclination multiple-film Weissenberg photographs of the $h 0-10 l$ reciprocal lattice nets taken with $\mathrm{Cu}-K_{\alpha}$ radiation. These data were corrected for spot shape, Lorentz, and polarization factors to yield 5325 independent structure amplitudes. No corrections were made for absorption or extinction. Initially the various layers of data were assumed to be on a common scale as each had been given similar exposure times. Absolute layer scales were established at the end of the isotropic refinement (vide infra) by correlation with the observed structure amplitudes.

Structure Analysis.-The initial position for the cerium atom was determined from the three-dimensional Patterson map, and approximate positions for the other non-hydrogen atoms were obtained from the cerium-phased ( $R \quad 0.36$ ) three-dimensional $F_{0}$ map. The identity of the sulphur atoms in three of the ligands was established on the basis of peak heights, but in the remaining ligand two peaks of approximately equal height appeared in possible positions. Since the sulphur atom was consistently cis-planar with respect to the adjacent $\mathrm{C}=\mathrm{O}$ group in three ligands, we decided to treat $\mathrm{S}(\mathrm{l})$ as a sulphur atom during the next series of calculations. The atomic positional and isotropic thermal parameters were then refined by full-matrix leastsquares calculations from $R 0.275$ to $R 0 \cdot 155$. During these iterations the large structure was refined in blocks, treating 37 atoms in any one cycle and rotating the atoms in alternate cycles. At the end of this refinement the temperature factor for $\mathrm{C}(4), B=1 \cdot 1 \AA^{2}$, was significantly less than those of the atoms to which it was bonded, $\mathrm{C}(3)$, $7 \cdot 4 \AA^{2} ; C(5), 4 \cdot 0 \AA^{2}$; while that for $\mathrm{S}(1)$ was high $\left(7 \cdot 8 \AA^{2}\right)$. These facts along with the earlier evidence from the electron density suggested that this thienyl group was disordered. A similar disordering of the thienyl moiety has been noted in 2-[(2)-dimethylaminoethyl-2-thienylamino]pyridine hydrochloride. ${ }^{5}$ Since our least-squares program does not allow for the refinement of atom occupation factors, we assumed $50 \%$ population of each of two orientations resulting from rotation about the $\mathrm{C}(5)-\mathrm{C}(6)$ bond, and employed the average atomic scattering factor $\left(f_{\mathrm{s}}+f_{\mathrm{C}}\right) / 2$ for both $\mathrm{S}(1)$ and $\mathrm{C}(4)$. It was possible to identify atom (64) in the isoquinolinium ion as the nitrogen atom from its relatively low temperature factor. The

according to the scheme $\sqrt{ } w=1$ for $\left|F_{0}\right| \leqslant 50$ and $\sqrt{ } w=50 /\left|F_{0}\right|$ for $\left|F_{0}\right|>50$, and this appeared to be adequate when $\left\langle w \Delta^{2}\right\rangle$ was analysed in ranges of $\left|F_{0}\right|$.

A Table of observed structure amplitudes and calculated structure factors has been deposited in Supplementary Publication No. SUP 20985 (25 pp., 1 microfiche).*

## RESULTS AND DISCUSSION

Figure 1 shows the molecular configuration in the asymmetric crystal unit and the atom numbering scheme employed. Interatomic distances and angles are reported in Table 2, and the results of mean plane calculations through groups of atoms are presented in Table 3.

The cerium atom is co-ordinated by eight oxygen atoms with $\mathrm{Ce}-\mathrm{O}$ distances ranging from 2.425 to $2.563 \AA$, and there are significant deviations from the mean of $2 \cdot 470 \AA$ which is close to the corresponding $\mathrm{M}-\mathrm{O}$ distance of $2.46 \AA$ in $\mathrm{NH}_{4}\left[\operatorname{Pr}(\mathrm{ttb})_{4}\right] \mathrm{H}_{2} \mathrm{O}^{8}$ and it is slightly longer than those of $2 \cdot 40$ and $2 \cdot 32 \AA$ in $\alpha^{-9}$ and $\beta-{ }^{10} \mathrm{Ce}(\mathrm{acac})_{\mathbf{4}}$ (acac $=$ acetylacetonate) and $2 \cdot 323 \AA$ in $\mathrm{Cs}\left[\mathrm{Y}(\mathrm{hfac})_{4}\right]^{11} \quad(\mathrm{hfac}=$ hexafluoroacetylacetonate). In spite of the significant distortions from ideal geometry it is still possible to recognize that the oxygen atoms surround the cerium atom in a distorted $D_{2 d}$ dodecahedral arrangement with the bidentate ligands spanning the $m$ edges (Hoard and Silverton ${ }^{1}$ notation, see Figure 2) of the trapezoids $\mathrm{O}(7) \mathrm{O}(10) \mathrm{O}(21) \mathrm{O}(24)$ and $\mathrm{O}(35)$ $\mathrm{O}(38) \mathrm{O}(49) \mathrm{O}(52)$ between which the $89.8^{\circ}$ angle is not significantly different from the ideal $D_{2 d}$ value of $90^{\circ} .{ }^{1,12}$ Moreover, the angular shape parameters $\theta_{\mathrm{A}}=$ $38 \cdot 7-48 \cdot 6^{\circ}$, mean $44 \cdot 4^{\circ}$, and $\theta_{B}=64.9-71 \cdot 0^{\circ}$, mean $67.9^{\circ}$, compare favourably with $\theta_{\mathrm{A}}=36.9^{\circ}, \theta_{\mathrm{B}}=69.5^{\circ}$

\end{array}
$$

calculated by Hoard and Silverton ${ }^{1}$ for the hard-sphere model. Normally, complexes of $D_{2 d}$ dodecahedral coordination have the order of magnitudes of the sides $g>a=m$ and bidentate ligands span the $m$ edges. ${ }^{13}$ However, noteworthy exceptions to this general rule have been reported for $\mathrm{NH}_{4}\left[\operatorname{Pr}(\mathrm{ttb})_{4}\right] \mathrm{H}_{2} \mathrm{O},{ }^{8} \mathrm{Cs}\left[\mathrm{Y}(\mathrm{hfac})_{4}\right]{ }^{11}$ and isomorphous $\mathrm{Cs}\left[\mathrm{Eu}(\mathrm{hfac})_{4}\right]^{14}$ and $\left.\mathrm{Cs}\left[\mathrm{Am}(\mathrm{hfac})_{4}\right]\right]^{14}$ where it has been found that $g=m<a$ and the bidentate ligands span the $g$ edges. We also find from the present study that $g=m<a$ but here the ligands span the $m$ edges. Inspection of the dodecahedral $b$ parameters (Table 2) reveals significant differences among them, especially noteworthy is the long $\mathrm{O}(21)-\mathrm{O}(38)$ distance of $4 \cdot 27 \AA$ which is a consequence of $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$
${ }^{13}$ See e.g. W. D. Bonds, jun., R. D. Archer, and W. C. Hamilton, Inorg. Chem., 1971, 8, 1764.
hydrogen bonding, $\mathrm{N} \cdots \mathrm{O}=2.87 \AA$, between the isoquinolinium ion and $\mathrm{O}(38)$ in the cerium co-ordination sphere. The presence of this hydrogen bonded association weakens the $\mathrm{Ce}-\mathrm{O}(38)$ interaction and increases the separation between these atoms to $2.563 \AA$ which is significantly longer than the $2 \cdot 470 \AA \mathrm{Ce}-\mathrm{O}$ mean; a concomitant reduction in the $\mathrm{Ce}-\mathrm{O}(10)=2.425$ and $\mathrm{Ce}-\mathrm{O}(49)=2 \cdot 426 \AA$ distances takes place. The net result is that the hydrogen bond causes significant distortion from a regular $D_{2 d}$ dodecahedral arrangement around the cerium atom, and molecular models show clearly that in the absence of this interaction a regular configuration can be attained when the $\mathrm{O}(21) \cdots \mathrm{O}(38)$ distance is restored to a more normal value. It is of note that the hydrogen bond involves an oxygen atom in the cerium(III) co-ordination sphere rather than one of the electronegative peripheral fluorine atoms which

(a)

(b)

Figure 2 The $D_{2 d}$ dodecahedron (a) from ref. 8, and (b) in $\left(\mathrm{C}_{8} \mathrm{H}_{4} \mathrm{~F}_{3} \mathrm{O}_{2} \mathrm{~S}\right)_{4} \mathrm{Ce}^{-}$with oxygen sites labelled
could act as proton acceptors. However, in addition to the hydrogen bond, the observed arrangement positions the positively charged nitrogen atom close to two fluorine atoms and another oxygen atom as shown in Figure 1. If we distinguish between the terminal groups of the ligands, then the $\mathrm{Ce}(\mathrm{ttb})_{4}{ }^{-}$anion has $C_{1}$ symmetry, for occupation of dodecahedral A and B sites by different ends of the ligands is not conserved in this complex. A like result was noted in the crystal structure of $\mathrm{NH}_{4}\left[\operatorname{Pr}(\mathrm{ttb})_{4}\right] \mathrm{H}_{2} \mathrm{O}^{8}$ where one of the ligands has its terminal groupings reversed.

The distances of the cerium atom from the $\beta$-diketone OCCCO least-squares planes are in Table 3. From these we find that the cerium atom is approximately coplanar with the other five atoms in two chelate rings, $\mathrm{C}(20)-\mathrm{O}(24)$ and $\mathrm{C}(34)-\mathrm{O}(38)$, whereas it is significantly displaced from the corresponding planes, $\mathrm{C}(6)-\mathrm{O}(10)$ and $\mathrm{C}(48)-\mathrm{O}(52)$, in the other two ligands, the displacements corresponding to folding of $18^{\circ}$ about the $\mathrm{O}-\mathrm{O}$ line. It has been pointed out elsewhere that while such folding is common it is not an essential feature ${ }^{15}$ of $\beta$-diketone complexes. The differences noted here may be ascribed to differences in the intra- and inter-molecular forces exerted on each of the ligands. In the $\beta$-diketone chelate rings the mean $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{O}$ distances, $1 \cdot 41$ and $1 \cdot 25 \AA$, and the mean $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angle $119 \cdot 5^{\circ}$, are compatible with the values expected for a delocalized system, and they are in satisfactory agreement with, for example, the

[^1]corresponding mean dimensions $1 \cdot 390(3), 1 \cdot 274(3) \AA$, and $124 \cdot 0(3)^{\circ}$ in a number of acetylacetonate complexes. ${ }^{16}$

Significant differences occur in the angles subtended at the carbonyl carbon atoms. Adjacent to the trifluoromethyl group the mean $\mathrm{C}-\mathrm{C}-\mathrm{O}$ ring angle is $131 \cdot 4^{\circ}$ whereas at the other end of the ligand the mean of the $\mathrm{C}-\mathrm{C}-\mathrm{O}$ angles is $126 \cdot 6^{\circ}$. The latter is close to that of $124.0^{\circ}$ in $\mathrm{NH}_{4}\left[\operatorname{Pr}(\mathrm{ttb})_{4}\right] \mathrm{H}_{2} \mathrm{O}^{8}$ and to the average of $125 \cdot 3(3)^{\circ}$ in acetylacetonate complexes. ${ }^{16}$ The angle at the trifluoromethyl group is in good agreement with the values found in other trifluoroacetate ligands, e.g., $129.7^{\circ}$ in $\mathrm{Cu}(\mathrm{hfac})_{2} \mathrm{H}_{2} \mathrm{O}$ (dmed) ${ }_{2}{ }^{17} \quad$ (dmed $=\mathrm{NN}$-dimethylethylenediamine), $132 \cdot 3^{\circ}$ in $\mathrm{Cs}\left[\mathrm{Eu}(\mathrm{hfac})_{4}\right]^{14}$ and
the $\mathrm{C}(5)-\mathrm{C}(6)$ bond. It is possible that the individual variations in the other three rings reflect some further disordering and that the isotropic model employed is an entirely inadequate description. In each ligand the thienyl rings are planar within the accuracy of the analysis, and their substituent carbon atoms lie close to the ring plane (Table 3). Dihedral angles between the intraligand thienyl and the OCCCO $\beta$-diketone planes range from 5 to $23^{\circ}$ and the variation is probably due to differences in crystal packing forces.

Evaluation of the torsion angles about the $\mathrm{C}-\mathrm{C}$ bonds at the trifluoromethyl groups indicates that a conformational preference exists, for in all four cases one fluorine

Figure 3 The crystal structure viewed in projection along the $b$-axis
$\mathrm{Cs}\left[\mathrm{Am}(\mathrm{hfac})_{4}\right]^{14}$ and $130 \cdot 4^{\circ}$ in $\mathrm{NH}_{4}\left[\operatorname{Pr}(\mathrm{htta})_{4}\right] \mathrm{H}_{2} \mathrm{O}$. Thus substitution of the methyl group by the more electronegative trifluoromethyl group results in an increase in $\beta$-diketone chelate ring angle at the carbon atoms bearing these groups.

The dimensions of chemically equivalent bonds and valency angles in the thienyl rings are in rather poor agreement and a detailed discussion is not justified. For one of these groups we assumed a $50 \%$ occupation of each of two orientations obtained by rotation about
${ }^{16}$ E. C. Lingafelter and R. L. Braun, J. Amer. Chem. Soc. 1966, 88, 2951.
atom lies close to trans-planar with respect to the adjacent $\beta$-diketone oxygen atom while the other two fluorine atoms are approximately equidistant from this atom. A similar result was noted in crystalline $\mathrm{NH}_{4}\left[\operatorname{Pr}(\mathrm{ttb})_{4}\right] \mathrm{H}_{2} \mathrm{O}$. In the trifluoromethyl groups the mean dimensions are $\mathrm{C}-\mathrm{F}=1.30 \AA, \mathrm{C}-\mathrm{C}-\mathrm{F}=113 \cdot 1^{\circ}$, and $\mathrm{F}-\mathrm{C}-\mathrm{F}=106 \cdot 3^{\circ}$. Although the mean $\mathrm{C}-\mathrm{F}$ bond length is notably shorter than the sum of the single bond covalent radii, ${ }^{18} 1.41 \AA$, it is not atypical for such bonds

in fluoroalkyl groups which are subject to substantial librational motion as in the present complex. ${ }^{17,19,20}$ The differences in $\mathrm{C}-\mathrm{C}-\mathrm{F}$ and $\mathrm{F}-\mathrm{C}-\mathrm{F}$ angles represent a consistent feature of trifluoromethyl groups. Corresponding values in some other complexes are 114 and $104^{\circ}$ in $\mathrm{Cs}\left[\mathrm{Y}(\mathrm{hfac})_{4}\right],{ }^{11} 112.9$ and $105.9^{\circ}$ in $\mathrm{Cu}(\mathrm{hfac})_{2} \mathrm{H}_{2} \mathrm{O}-$ (dmed) $)_{2},{ }^{17} 112$ and $104^{\circ}$ in $\mathrm{Cu}(\mathrm{hfac})_{3}{ }^{-} .{ }^{19}$ In hfacH and hexafluoroacetic anhydride ${ }^{21}$ the respective values are 110.6 and $108.3^{\circ}$ and 110.2 and $108.7^{\circ}$.

The atoms of the isoquinolinium cation are approximately coplanar as would be expected and the mean bond lengths and angles compare favourably with normal values. ${ }^{22}$

A view of the molecular packing in the crystal is shown in Figure $\mathbf{3}$ and the shorter intermolecular separations are in Table 2. Apart from the short NH $\cdot \cdot$ O hydrogen bonded separation (vide supra) the distances correspond to normal van der Waals separations.

The extensive crystallographic calculations were carried out on the IBM 370/165 computer located at the Triangle Universities Computation Centre, Research Triangle Park, North Carolina. We thank Dr. F. E. Mabbs for supplying the crystals used for this analysis.
