# Crystal and Molecular Structures of Dinitrato(1,10-phenanthroline)copper(II) and Diaquanitrato(1,10-phenanthroline)copper(II) Nitrate 

By Dennis L. McFadden and Andrew T. McPhail,* Paul M. Gross Chemical Laboratory, Duke University, Durham, North Carolina 27706, U.S.A.

#### Abstract

The crystal structures of the title compounds, (I) [ $\mathrm{Cu}\left(\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{~N}_{2}\right)\left(\mathrm{NO}_{3}\right)_{2}$ ] and (II) $\left[\mathrm{Cu}\left(\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{~N}_{2}\right)\left(\mathrm{NO}_{3}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ $\left[\mathrm{NO}_{3}\right]$, have been determined from three-dimensional $X$-ray diffractometer data and refined by full-matrix leastsquares calculations to $R 0.045$ [(I), 1181 reflections] and 0.058 [(II), 1525 reflections]. Crystals of (I) and (II) are monoclinic, space group $P 2_{1} / c$, with $Z=4$ in cells of dimensions: (I) $a=8.76(1)$. $b=9.12(1), c=17.63(1) \AA, \beta=107.4(1)^{\circ}$ : (II) $a=7.03(1), b=20.20(1), c=11.49(1) \AA, \beta=109.9(1)^{\circ}$. Crystals of (I) contain polymeric $\mathrm{Cu}\left(\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{~N}_{2}\right)\left(\mathrm{NO}_{3}\right)_{2}$ units in which one of the nitrato-groups is terdentate and serves to bridge the units along the $2_{1}$ screw axis. The copper atom is seven co-ordinate: $\mathrm{Cu}-\mathrm{N}$ (phen) $1.994(5), 2.018(5): \mathrm{Cu}-\mathrm{O}\left(\mathrm{NO}_{3}\right) 1.960(5), 1.996(4), 2.326(4), 2.814(5)$, and 2.863(5) $\AA$. In (II) the copper atom is in a distorted octahedral environment with $\mathrm{Cu}-\mathrm{N}$ (phen) 2.005(6), 2.008(6), $\mathrm{Cu}-\mathrm{O}\left(\mathrm{NO}_{3}\right) 1.983(5)$, and $\mathrm{Cu}-\mathrm{O}\left(\mathrm{H}_{2} \mathrm{O}\right) 2.005(6) \AA$ defining the basal plane. A second water oxygen [ $\mathrm{Cu}-\mathrm{O}$ $2.261(6) \AA$ ]. and an oxygen of the asymmetrically bidentate nitrato-group [Cu-O 2.594(6) $\AA$ ] occupy the axial sites. The nitrate ion is involved in three hydrogen bonds to the co-ordinated water molecules.

The reaction of 1,10 -phenanthroline (phen) with a large excess of copper(II) nitrate in ethanol was reported ${ }^{1}$ to yield a $1: 1$ complex. As part of our continuing studies on the co-ordination geometry of first-row transition metals with bidentate ligands, we repeated the described procedure and found it to yield two crystalline complexes, $\left[\mathrm{Cu}(\right.$ phen $\left.)\left(\mathrm{NO}_{3}\right)_{2}\right](\mathrm{I})$, and $\left[\mathrm{Cu}(\right.$ phen $\left.)\left(\mathrm{NO}_{3}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]-$ $\left[\mathrm{NO}_{3}\right]$ (II), which we have subjected to single-crystal $X$-ray analysis to investigate the nature of the metalatom co-ordination.

## EXPERIMENTAL

The complexes were prepared by addition of an ethanolic solution of 1,10 -phenanthroline monohydrate $(0.28 \mathrm{~g}$, $0.0014 \mathrm{~mol})$ to a solution of $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}, 3 \mathrm{H}_{2} \mathrm{O}(0.25 \mathrm{~mol})$ in a minimum of ethanol. The solid which precipitated overnight and which contained a few small dark blue crystals of (I) was filtered off and the filtrate set aside to evaporate slowly. After several days long fibrous pale blue crystals of (II) were harvested in large yield. The filtrate was allowed to evaporate further and more large dark blue crystals of (I) formed.

Crystal Data.-(I), $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{CuN}_{4} \mathrm{O}_{6}, \quad M=359.7$, Monoclinic, $\quad a=8.76(1), \quad b=9.12(1), \quad c=17.63(1) \quad \AA, \quad \beta=$ $107.4(1)^{\circ}, \quad U=1344 \AA^{3}, D_{\mathrm{c}}=1.78, Z=4, D_{\mathrm{m}}=1.75$, $F(000)=740$. Mo- $K_{\alpha}$ radiation, $\lambda=0.71069 \AA \begin{aligned} & \text { i }\end{aligned} \mu(\mathrm{Mo}-$ $\left.K_{\alpha}\right\rangle=13.7 \mathrm{~cm}^{-1}$. Space group $P 2_{1} / c\left(C_{2 h}^{5}\right)$ from systematic absences: $h 0 l$ when $l \neq 2 n, 0 k 0$ when $k \neq 2 n$.
(II), $\mathrm{C}_{12} \mathrm{H}_{12} \mathrm{CuN}_{4} \mathrm{O}_{8}, M=403.7$, Monoclinic, $a=7.03(1)$, $b=20.20(1), \quad c=11.49(1) \quad \AA, \quad \beta=109.9(1)^{\circ}, \quad U=1534$ $\AA^{3}, D_{\mathrm{c}}=1.75, Z=4, D_{\mathrm{m}}=1.72, F(000)=1108 . \mathrm{Mo}-K_{\alpha}$ radiation, $\mu\left(\mathrm{Mo}-K_{\alpha}\right)=15.3 \mathrm{~cm}^{-1}$. Space group $P 2_{1} / c$ $\left(C_{2 h}^{5}\right)$ from systematic absences: $h 0 l$ when $l \neq 2 n, 0 k 0$ when $k \neq 2 n$.

Crystallographic Measurements.-For both complexes preliminary unit cell dimensions and space-group information were obtained from precession photographs taken with Mo $-K_{\alpha}$ radiation, and rotation and Weissenberg photographs taken with $\mathrm{Cu}-K_{\alpha}(\lambda=1.542 \AA)$ radiation.

Single crystals of dimensions (I) ca. $0.6 \times 0.2 \times 0.15 \mathrm{~mm}$ and (II) ca. $0.2 \times 0.3 \times 1.2 \mathrm{~mm}$ were oriented on glass fibres such that the [ $10 \overline{\mathrm{I}}]$ direction for (I) and the [305] direction for (II) were parallel to the $\phi$ axis of an EnrafNonius CAD 3 automated diffractometer ( Zr -filtered $\mathrm{Mo}-K_{\alpha}$

[^0] issue.
radiation, take-off angle $3^{\circ}$ ). Refined cell parameters were obtained from least-squares treatment of the $\theta, \phi$, and $\chi$ angles for 25 (I) and 36 (II) high-order reflections. Intensities for all unique reflections having $2 \theta<50^{\circ}$ were collected by the $\theta-2 \theta$ scanning technique as described previously, ${ }^{2}$ with scanwidths $(0.90+0.40 \tan \theta)^{\circ}$ for (I) and $(1.60+0.50 \tan \theta)^{\circ}$ for (II). Instrument and crystal stability were monitored throughout data collection by remeasuring the intensity of a standard strong reflection periodically and no significant variation was noted. Only those reflections for which $I>2.0 \sigma(I)$, where $\sigma^{2}(I)=$ (scan count + total background count), were corrected for Lorentz and polarization effects to yield 1181 (I) and 1525 (II) reflections which were used in the structure solutions and refinements; no allowance was made for absorption.

Structure Analysis.-The structures were solved by the heavy-atom method. In each case copper atom co-ordinates were determined from the three-dimensional Patterson map and the non-hydrogen atoms were located in copper-phased $\left[\begin{array}{ll}R & \text { (I) } 0.42, R \\ \text { (II) } & 0.54]\end{array}\right.$ three-dimensional $F_{0}$ Fourier syntheses. Refinement of the positional and thermal parameters, at first isotropic and subsequently anisotropic, reduced $R(\mathrm{I})$ to 0.051 and $R(\mathrm{II})$ to 0.074 . 1,10-Phenanthroline hydrogen-atom positions were then calculated assuming $\mathrm{C}-\mathrm{H} 1.05 \AA$ and ideal geometry at the carbon atoms, and confirmed to coincide with regions of significant positive electron density in the difference-Fourier syntheses. For (I), least-squares adjustment of hydrogen-atom positions and isotropic thermal parameters produced meaningful results except for $\mathrm{H}(6)$ and $\mathrm{H}(7)$ which were therefore placed at their calculated positions. Several further cycles of least-squares calculations brought the refinement of (I) to convergence at $R 0.045$. For (II), the water hydrogen atoms were placed to coincide with electron-density maxima in the difference map. Attempts to refine the hydrogenatom parameters did not yield acceptable results and so they were all included in the subsequent calculations with fixed positions and $B 5.0 \AA^{2}$. Refinement of (II) converged at $R 0.058$ following several further rounds of least-squares adjustment of the non-hydrogen atom parameters.

Final atomic co-ordinates and thermal parameters are listed in Tables 1 and 2. Observed and calculated structure factors for both complexes are in Supplementary Publication No. SUP 21377 (16 pp., 1 microfiche). $\dagger$ For all

structure-factor calculations neutral-atom scattering factors for copper, carbon, nitrogen, and oxygen were those from ref. 3 with anomalous dispersion corrections ${ }^{4}$ included; for hydrogen the scattering factor of ref. 5 was used. In the least-squares calculations, $\Sigma w \Delta^{2}$ was minimized, with weights $w$ being assigned according to the scheme $\sqrt{ } w=1$ for $\left|F_{0}\right| \leqslant 20.0$ and $\sqrt{ } w=20.0 /\left|F_{0}\right|$ for $\left|F_{\mathrm{o}}\right|>20.0$ and showed no systematic dependence of $\left\langle w \Delta^{2}\right\rangle$ when analyzed in ranges of $\left|F_{0}\right|$.

## RESULTS AND DISCUSSION

The immediate environment of the copper atoms and the atom numbering schemes in (I) and (II) are shown in Figures 1 and 2. Interatomic distances and angles are
${ }^{3}$ D. T. Cromer and J. T. Waber, Acta Cryst., 1965, 18, 104.
4 'International Tables for $X$-Ray Crystallography,' vol. III, Kynoch Press, Birmingham, 1962.
in Table 3, and displacements of selected atoms from various least-squares planes in Table 4.

Crystals of (I) contain polymeric $\mathrm{Cu}(\mathrm{phen})\left(\mathrm{NO}_{3}\right)_{2}$ units in which one of the nitrato-groups is terdentate and serves to bridge these units in a syn-anti manner along the $2_{1}$ screw axis. The shortest $\mathrm{Cu} \cdots \mathrm{Cu}$ separation [5.233(1) $\AA$ ] within the polymer chain implies no direct metal-metal interaction. Figure 3 shows a view of the crystal packing.

Crystals of (II) comprise discrete $\left[\mathrm{Cu}(\mathrm{phen})\left(\mathrm{NO}_{3}\right)\right.$ $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{+}$cations and nitrate anions bridged by the coordinated water molecules (Figure 4).

Copper Co-ordination Geometry.-(I). The copper atom is co-ordinated by five oxygen atoms from three

co-ordination geometry in (I) bears a strong similarity to that found ${ }^{7}$ around the copper atom in dimeric $\left[\mathrm{Cu}(\mathrm{py})_{2}\left(\mathrm{NO}_{3}\right)_{2}\right], \mathrm{py}(\mathrm{py}=$ pyridine) where two transrelated pyridine nitrogen atoms [ $\mathrm{Cu}-\mathrm{N} \quad 1.995(7)$ and $2.006(8) \AA$ ] and two nitrato-oxygen atoms $[\mathrm{Cu}-\mathrm{O}$

$2.035(6)$ and $2.042(6) \AA$ ] define the equatorial plane, one nitrato-oxygen atom at $2.542(8) \AA$ occupies an axial site, and two other oxygen atoms at $2.618(8)$ and 2.906(7) $\AA$ complete the co-ordination.
(II). The copper atom is in a distorted octahedral environment where two nitrogen atoms of the bidentate 1,10-phenanthroline ligand $[\mathrm{Cu}-\mathrm{N}(1) \quad 2.005(6)$ and $\mathrm{Cu}-\mathrm{N}(10) 2.008(6) \AA$ ], one oxygen atom of an asymmetrically bidentate nitrato-group $[\mathrm{Cu}-\mathrm{O}(12) 1.983(5) \AA]$, and one water molecule oxygen $[\mathrm{Cu}-\mathrm{O}(16) 2.005(6) \AA]$ define the equatorial plane. Occupying one of the axial sites is the second water molecule $[\mathrm{Cu}-\mathrm{O}(15) 2.261(6) \AA]$, while an oxygen atom of the nitrato-group [Cu-O(14) 2.594(6)

Figure 4 Crystal structure of (II), viewed in projection along the $a$ axis; hydrogen bonds are denoted by broken lines
$\AA$ ] completes the metal-ion co-ordination. The mean $\mathrm{Cu}-\mathrm{N}$ distance $[2.007(6) \AA]$ is in excellent agreement with that $[2.006(5) \AA]$ for $\left[\mathrm{Cu}(\right.$ phen $\left.)\left(\mathrm{NO}_{3}\right)_{2}\right]$.

Nitrate Geometry.-The atoms in each of the nitratogroups and the nitrate ion are coplanar and, in accord with the commonly observed geometry, the copper atom lies close to the least-squares planes through the nitratogroups (Table 4). The dihedral angle between the nitrato-planes in (I) is $87.7^{\circ}$.

The mean nitrato N -O lengths [ 1.246 (I), $1.241 \AA$ (II)] are in excellent agreement with the mean of the means $[1.246(6) \AA]$ from several recent accurate determinations. ${ }^{8-12}$ The mean nitrate ion $\mathrm{N}-\mathrm{O}$ bond length

${ }_{12}$ A. F. Cameron, D. W. Taylor, and R. H. Nuttall, J.C.S. Dalton, 1973, 2130.
$(1.213 \AA)$ is slightly smaller than the nitrato-mean, probably due to neglect of correction for the more severe effects of thermal motion.

In both complexes the nitrato-groups act as asymmetrically bidentate ligands with respect to the same copper atom. Moreover, in (I) one group serves also to bridge the $\mathrm{Cu}($ phen $)\left(\mathrm{NO}_{3}\right)_{2}$ units along the $2_{1}$ screw axis so that all three oxygen atoms are co-ordinated to copper atoms. In accord with previous observations for other nitrato-complexes, ${ }^{13}$ the individual $\mathrm{N}-\mathrm{O}$ lengths in (I) and (II) differ significantly, their values reflecting the extent of the bonding interaction with the copper atom. Thus, the shorter is the $\mathrm{Cu}-\mathrm{O}$ distance, the stronger is the bonding interaction and the longer (weaker) is the $\mathrm{N}-\mathrm{O}$ bond. In (I) the distances are $\mathrm{Cu}-\mathrm{O}(12) 1.960(5)$, $\mathrm{N}(11)-\mathrm{O}(12) 1.294(8) ; \quad \mathrm{Cu}-\mathrm{O}(16) 1.996(4), \mathrm{N}(15)-\mathrm{O}(16)$ 1.289(7); $\quad \mathrm{Cu}-\mathrm{O}\left(17^{\mathrm{I}}\right) \quad 2.326(4), \quad \mathrm{N}(15)-\mathrm{O}(17) \quad 1.233(7)$; $\mathrm{Cu}-\mathrm{O}(18) \quad 2.814(5), \quad \mathrm{N}(15)-\mathrm{O}(18) \quad 1.230(7) ; \quad \mathrm{Cu}-\mathrm{O}(14)$ $2.863(5), \mathrm{N}(11)-\mathrm{O}(14) 1.202(9) \AA$; and in (II) they are $\mathrm{Cu}-\mathrm{O}(12) \quad 1.983(5), \quad \mathrm{N}(11)-\mathrm{O}(12) \quad 1.269(9) ; \quad \mathrm{Cu}-\mathrm{O}(14)$ $2.594(6), \mathrm{N}(11)-\mathrm{O}(14) 1.237(7) \AA$. Additionally, the $\mathrm{O}-\mathrm{N}-\mathrm{O}$ valency angles reveal distortions from $120^{\circ}$ in the direction that the largest $\mathrm{O}-\mathrm{N}-\mathrm{O}$ interbond angle is always opposite to the longest $\mathrm{N}-\mathrm{O}$ bond and vice versa. Examples of this in (I) are $\mathrm{N}(11)-\mathrm{O}(12) 1.294(8)$ $\AA$ and $\mathrm{O}(13)-\mathrm{N}(11)-\mathrm{O}(14) 125.1(7)^{\circ}, \mathrm{N}(11)-\mathrm{O}(14) 1.202-$ (9) $\AA$ and $\mathrm{O}(12)-\mathrm{N}(11)-\mathrm{O}(13) 115.9(6)^{\circ}$; other lengths and angles assume appropriate values consistent with this pattern. Similar observations have been noted for a number of other nitrato-complexes and may be rationalized ${ }^{13}$ in terms of the electron-pair repulsion model and the amount of nitrogen $p$ character in the bonds involved.

1,10-Phenanthroline Ligands.-In the 1,10-phenanthroline ligands the means of chemically equivalent bonds, assuming $C_{2 v}$ symmetry, are $\mathrm{N}(1)-\mathrm{C}(2) 1.321(9)$ [1.322(11)], $\mathrm{N}(1)-\mathrm{C}(10 \mathrm{~b}) 1.364(8)[1.375(10)], \mathrm{C}(2)-\mathrm{C}(3) 1.400-$ (10) $[1.395(13)], \mathrm{C}(3)-\mathrm{C}(4) 1.349(10)$ [1.377(14)], C(4)$\mathrm{C}(4 \mathrm{a}) 1.420(9)$ [1.394(13)], C(4a)-C(5) 1.432(9) [1.431(12)], $\mathrm{C}(4 \mathrm{a})-\mathrm{C}(10 \mathrm{~b}) \quad 1.398(9) \quad[1.397(11)], \mathrm{C}(5)-\mathrm{C}(6) \quad 1.351(10)$ [1.357(13)], C(10a)-C(10b) $1.421(8)[1.427(11)] \AA$, where

[^1]values in square brackets are for (II) and the other values are for (I) (the quoted standard deviations in parentheses for the mean of a pair of lengths is the larger of the individual values derived from the least-squares calculations). These distances correlate well with the bond orders predicted ${ }^{14}$ for phenanthrene from considerations of the contributions of various resonance forms. They are also not significantly different from the corresponding mean values computed ${ }^{15}$ from the results of a number of investigations: $1.34(3), 1.37(4), 1.42(4), 1.36(3), 1.41(3)$, $1.44(3), 1.43(4), 1.34(3)$, and $1.42(4) \AA$. In each complex the ligand atoms deviate significantly from coplanarity. For (I) the displacements (Table 4) indicate that the ligand is folded approximately about the line joining the mid-points of the $C(5)-C(6)$ and $C(10 a)-C(10 b)$ bonds. In contrast to this the atom displacements of (II) indicate that while there is symmetric buckling about these same mid-points there is bending about the $C(4 a) \cdots C(6 a)$ line in addition to the same type of folding as in (I), presumably in response to crystalpacking forces.

Crystal Packing.-The majority of the shorter intermolecular separations (Table 3) between polymer chains in (I) and ions in (II) involve oxygen atoms and correspond in (I) to normal van der Waals interactions. The shorter $\mathrm{O} \cdots \mathrm{O}$ separations in (II) imply that all the water hydrogen atoms participate in hydrogen bonds The equatorial water molecule bridges nitrate ions related by the $c$ glide plane, $\mathrm{O}(16) \cdots \mathrm{O}(18) 2.75, \mathrm{O}(16) \cdots \mathrm{O}(20)$ $2.73 \AA, O(18) \cdots O(16) \cdots O(20) 114.6^{\circ}$. The axial water molecule is hydrogen bonded to nitrate and nitratooxygen atoms thereby bridging ions along the $a$ direction: $\mathrm{O}(15) \cdots \mathrm{O}(14) 2.78, \mathrm{O}(15) \cdots \mathrm{O}(18) 2.88 \AA$, $\mathrm{O}(14) \cdots \mathrm{O}(15) \cdots \mathrm{O}(18) 70.9^{\circ}$.
