# Displacement of Chelate Ligands from Four-co-ordinate Complexes. Part IV. ${ }^{1}$ Reactions of (3-Azapentane-1,5-diamine)- and (3-Methyl-3-azapentane-1,5-diamine)-chlorogold(III) Complexes 

By Giuliano Annibale, Giovanni Natile,* and Lucio Cattalini, Istituto di Chimica Generale ed Inorganica, University of Venice, Italy
The kinetics of nucleophilic displacement of the chelate ligands 3-azapentane-1.5-diamine(3NH-pd) and 3-methyl3 -azapentane-1.5-diamine (3NMe-pd) from the complexes [AuCl $\mathrm{N}-\mathrm{N}-\mathrm{N}$ ) $] \mathrm{Cl}_{2}$ ( $\mathrm{N}-\mathrm{N}-\mathrm{N}=3 \mathrm{NH}$ - or $3 \mathrm{NMe}-\mathrm{pd}$ ) have been studied in $5 \%$ water-methanol solution at $25^{\circ} \mathrm{C}$. Under the experimental conditions used for the kinetic runs the predominant species in solution are $\left[\mathrm{AuCl}_{2}(\mathrm{HN}-\mathrm{N}-\mathrm{N})\right]^{2+}$ and $\left[\mathrm{AuCl}_{3}\left(\mathrm{H}_{2} \mathrm{~N}-\mathrm{N}-\mathrm{N}\right)\right]^{2+}$ in which the polydentate ligand acts as bi- and uni-dentate. The observed rate equation in both cases is formally analogous to that found in displacement of $N N N^{\prime} N^{\prime}$-tetraethylethylenediamine (teen) and $N N N^{\prime} N^{\prime}$-tetramethylethylenediamine (tmen) from the complexes $\left[\mathrm{AuCl}_{2}(\mathrm{~N}-\mathrm{N})\right]\left(\mathrm{ClO}_{4}\right](\mathrm{N}-\mathrm{N}=$ teen or tmen) and is in accord with the mech-

$$
\begin{equation*}
\left[\mathrm{AuCl}_{2}(\mathrm{HN}-\mathrm{N}-\mathrm{N})\right]^{2+} \stackrel{K_{1}\left[\mathrm{Cl}^{-}\right]}{\rightleftharpoons}\left[\mathrm{AuCl}_{3}(\mathrm{HN}-\mathrm{N}-\mathrm{N})\right]^{+} \stackrel{K_{2}\left[\mathrm{H}^{+}\right]}{\rightleftharpoons}\left[\mathrm{AuCl}_{3}\left(\mathrm{H}_{2} \mathrm{~N}-\mathrm{N}-\mathrm{N}\right)\right]^{2+} \xrightarrow{k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]} \tag{i}
\end{equation*}
$$

$\left[\mathrm{AuCl}_{4}\right]-+\left[\mathrm{H}_{3} \mathrm{~N}-\mathrm{N}-\mathrm{N}\right]^{3+}$
anism in equation (i). From the kinetic data the values of $K_{1}, K_{2}$, and $K_{3}{ }^{\prime}$ have been determined, and the $K\left[\mathrm{H}^{+}\right]\left[\mathrm{Cl}^{-}\right]$
$[\mathrm{AuCl}(\mathrm{N}-\mathrm{N}-\mathrm{N})]^{2+} \xlongequal{ }\left[\mathrm{AuCl}_{2}(\mathrm{HN}-\mathrm{N}-\mathrm{N})\right]^{2+}$
constant for equilibrium (ii) has been measured spectrophotometrically. The complex $[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+}$ undergoes deprotonation of one of the two co-ordinated primary amine groups and the $\mathrm{p} K_{\mathrm{a}}$ values, determined in $\left.0.5 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}^{2} \mathrm{ClO}_{4}\right]$ and in $0.5 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaCl}$, are reported.

The displacement of bidentate $N N N^{\prime} N^{\prime}$-tetraethylethylenediamine (teen) and $N N N^{\prime} N^{\prime}$-tetramethylethylenediamine (tmen) from the gold complexes $\left[\mathrm{AuCl}_{2}(\mathrm{~N}-\mathrm{N})\right]^{+}$ ( $\mathrm{N}-\mathrm{N}=$ teen or tmen) has been shown to occur in two consecutive steps each proceeding through the normal associative mechanism. ${ }^{2}$ Also the displacement of a tridentate ligand could proceed in an analogous way, but in this case the first ring opening could be favoured by the steric strain of the two condensed five-membered rings, and once the first ' tooth' is freed its protonation could facilitate the displacement of the adjacent one.

The substitution of 3 -azapentane-1,5-diamine ( 3 NH pd ) and $N N N^{\prime} N^{\prime}$-tetraethyl-3-azapentane-1,5-diamine (3NH-tepd) by chloride ion from $[\mathrm{PdCl}(\mathrm{N}-\mathrm{N}-\mathrm{N})]^{+}$ ( $\mathrm{N}-\mathrm{N}-\mathrm{N}=3 \mathrm{NH}-\mathrm{pd}$ or - tepd) has been studied by Poë and Vaughan ${ }^{3}$ and found to be a two-stage process. In the first stage an intermediate, in which the polyamine is unidentate and the uncomplexed nitrogen atoms are all protonated, is formed. In the second stage the unidentate ligand is displaced through a complex reaction mechanism which is completely different from that normally observed for displacement of unidentate amines from square-planar substrates. ${ }^{4}$ Ring opening and formation of species in which a potentially tridentate amine is only bidentate has been considered for both palladium(II) ${ }^{5}$ and gold(III) complexes. ${ }^{6,7}$

Having previously studied the displacement of diamines from gold(III) complexes, ${ }^{1,2,8}$ we have extended the investigation to triamines with the hope of evaluating, under favourable conditions, the equilibrium and/or kinetic constants of the various dissociation steps. The

complex $[\mathrm{AuCl}(3 \mathrm{NH}-\mathrm{pd})]^{2+}$ is also known to undergo deprotonation of the central NH nitrogen. ${ }^{9}$ The acidic properties of the terminal nitrogen atoms could be investigated by reacting the gold complex of 3-methyl-3-azapentane-1,5-diamine ( 3 NMe -pd) with bases.

## EXPERIMENTAL

Hydrogen tetrachloroaurate(III) trihydrate was obtained from Johnson, Matthey and Co.; solvents, inorganic salts, and 3 -azapentane-1,5-diamine trihydrochloride were all reagent-grade products. 3 -Methyl-3-azapentane-1,5-diamine was prepared according to a reported procedure. ${ }^{10}$
Preparation of Complexes.-The salt $[\mathrm{AuCl}(3 \mathrm{NH}-\mathrm{pd})] \mathrm{Cl}_{2}$ was first prepared by Baddley et al., ${ }^{9}$ but we used a slightly different procedure. To a solution of $\mathrm{HAuCl}_{4} \cdot 3 \mathrm{H}_{2} \mathrm{O}(1.00 \mathrm{~g}$, $2.5 \mathrm{mmol})$ in water $\left(2 \mathrm{~cm}^{3}\right)$, cooled in an ice bath, was added, with stirring, $3 \mathrm{NH}-\mathrm{pd} \cdot 3 \mathrm{HCl}(1.4 \mathrm{~g}, 6.5 \mathrm{mmol})$. A yellow complex was first precipitated. To the reaction mixture was then added dropwise $\mathrm{Na}[\mathrm{OH}](0.46 \mathrm{~g}, 11.6 \mathrm{mmol})$ dissolved in water ( $2 \mathrm{~cm}^{3}$ ). The complex which initially precipitated redissolved and after stirring for 2 h at $0^{\circ} \mathrm{C}$ a crystalline yellow complex separated from the solution; this was filtered off, washed twice with ethanol, and dried over phosphorus penta-oxide. At this stage the yield was less than $50 \%$; the complete precipitation of the complex was achieved by adding ethanol $\left(5 \mathrm{~cm}^{3}\right)$ to the mother liquor \{Found: C, $11.7 ; \mathrm{H}, 3.3 ; \mathrm{Cl}, 26.3 ; \mathrm{N}, 10.3$. $\mathrm{AuCl}-$ ( $3 \mathrm{NH}-\mathrm{pd}$ ) $] \mathrm{Cl}_{2}$ requires $\left.\mathrm{C}, 11.8 ; \mathrm{H}, 3.2 ; \mathrm{Cl}, 26.2 ; \mathrm{N}, 10.3 \%\right\}$. The complex $[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})] \mathrm{Cl}_{2}$ was prepared similarly. \{Found: C, 14.0; H, 3.9; Cl, 25.1; N, 9.7. [AuCl(3NMepd) $\mathrm{Cl}_{2}$ requires $\left.\mathrm{C}, 14.3 ; \mathrm{H}, 3.6 ; \mathrm{Cl}, 25.3 ; \mathrm{N}, 10.0 \%\right\}$.

Kinetics.-Rate data were obtained spectrophotometrically by measuring changes in absorbance with time using an

[^0]Optica CF4R double-beam instrument. Separate solutions of complex and reagents were prepared in methanol containing $5 \%$ of water, brought to reaction temperature, mixed, and placed in the thermostatted cell of the spectrophotometer. The concentrations of chloride and perchloric acid were determined by standard titrimetric methods; all kinetic runs were in the presence of excess of entering reagents and at constant ionic strength. First-order rate constants were calculated from plots of $\ln \left(A_{\infty}-A_{t}\right)$ against time, where $A_{t}$ and $A_{\infty}$ are absorbances at time $t$ and after at least six half-lives respectively. These plots were linear for at least four half-lives. The experimentally determined rate constants, $k_{\text {obs. }} / \mathrm{s}^{-1}$, are summarized in Tables 1 and 3.

From the values of $k_{\text {obs. }}$ the parameters $B_{0}$ and $B_{1}$ (Tables 2 and 4) were calculated from least-squares fits and the uncertainties quoted are $95 \%$ confidence limits. The constants $r, s$, and $t$ (see text) were derived from $B_{0}$ and $B_{1}$ using an unweighted least-squares fit and their uncertainties were derived from those of $B_{0}$ and $B_{1}$ using the formula for indirect error.

Measurement of the Equilibrium Constant, K, for the $K[\mathrm{H}+\mathrm{I}[\mathrm{Cl}-]$ equilibrium: $\quad[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{++} \xrightarrow{K\left[\mathrm{H}+1 \mathrm{Cl}^{-}\right]}\left[\mathrm{AuCl}_{2}(3 \mathrm{NMe}-\right.$ $\mathrm{Hpd})]^{2+}$.-At a given $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]$, all the species involved in equilibria contribute to the total absorbance $A_{i}$. Since

$$
\begin{aligned}
& {[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+}(\mathrm{I}) \stackrel{K\left[\mathrm{H}^{+}\right][\mathrm{Cl}-\mathrm{l}}{\rightleftharpoons}\left[\mathrm{AuCl}_{2}(3 \mathrm{NMe}-\mathrm{Hpd})\right]^{2+}(\mathrm{II})} \\

the experiment, the species $\left[\mathrm{AuCl}_{2}(3 \mathrm{NMe}-\mathrm{pd})\right]^{+}$has not been considered. Using low values of [ $\mathrm{Cl}^{-}$] $\left(<0.3 \mathrm{~mol} \mathrm{dm}^{-3}\right)$ and short experimental times, $\left[\mathrm{AuCl}_{4}{ }^{-}\right]$can also be assumed to be
${ }^{11}$ M. J. Carter and J. K. Beattie, Inorg. Chem., 1970, 9, 1233.
12 G. Natile, G. Albertin, E. Bordignon, and A. A. Orio, J.C.S. Dalton, 1976, 626.
small. Moreover one experiment made at $\left[\mathrm{Cl}^{-}\right]=0.03 \mathrm{~mol}$ $\mathrm{dm}^{-3}$ and various $\left[\mathrm{H}^{+}\right]\left(0.3<\left[\mathrm{H}^{+}\right]<1.5 \mathrm{~mol} \mathrm{dm}{ }^{-3}\right)$ has shown that equilibrium mixtures of (II) -(IV) of different compositions [ranging from (1) 2, (II) 58 , (III) 3.5 , and (IV) $36.5 \%$ to (I) 0.2 , (II) 24, (III) 1.5 , and (IV) $74.5 \%$ ] do not give appreciable changes in absorbance near 280 nm . Therefore, knowing the value of the absorbance at low $\left[\mathrm{H}^{+}\right]$ and $\left[\mathrm{Cl}^{-}\right]\left(A_{\min }\right)$ where $(\mathrm{I})$ is the predominant species and the value of absorbance at high $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]\left(A_{\text {max }}\right)$ where species (II)-(IV) predominate, by measuring the actual absorbance $\left(A_{i}\right)$ at the same wavelength ( 284 nm ) as a function of $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]$, the value of $K$ can be evaluated

$$
\left(A_{i}-A_{\min }\right) /\left(A_{\max }-A_{i}\right)=
$$

from equation (1) ( $K_{1}$ and $K_{2}$ being known from kinetic data).

Acid-Base Titrations.-The salt $[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})] \mathrm{Cl}_{2}$ behaves as an acid and can be titrated with sodium hydroxide. The titration was made in a beaker thermostatted at $25.0 \pm 0.1^{\circ} \mathrm{C}$. A Metrohm Herisau model E500 digital pH meter, in conjunction with a glass electrode, was used to measure the pH . Immediately prior to the titrations the pH meter was standardized with buffer solutions at pH 3.56 (saturated potassium tartrate) and at $\mathrm{pH} 7.00\left(50 \mathrm{~cm}^{3}\right.$ of 0.1 mol dm ${ }^{-3} \mathrm{~K}\left[\mathrm{H}_{2} \mathrm{PO}_{4}\right]$ and $29.1 \mathrm{~cm}^{3}$ of $\left.0.1 \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{Na}[\mathrm{OH}]\right)$. A microburette ( $5 \mathrm{~cm}^{3}$ ) was used to add the titrant ( 0.2 mol $\mathrm{dm}^{-3} \mathrm{Na}[\mathrm{OH}]$ ) to the solution of the complex (ca. 5 mmol in $25 \mathrm{~cm}^{3}$ of water). The volume change during the titration was less than $10 \%$. Complex solutions containing 0.5 mol $\mathrm{dm}^{-3} \mathrm{NaCl}$ in the first case and $0.5 \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{Na}\left[\mathrm{ClO}_{4}\right]$ in the second were used.

## RESULTS

Figure $1(a)$ gives the absorbance of a $3.5 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$ solution of $[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+}$ in $1.82 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{LiCl}$ and $10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HClO}_{4}\left(I=1.7 \mathrm{~mol} \mathrm{dm}{ }^{-3},{\left.\mathrm{Li}\left[\mathrm{ClO}_{4}\right]\right) \text {. }}^{2}\right.$ The presence of $\mathrm{Cl}^{-}$prevents the hydrolysis of the metalchlorine bond, and the acidic medium is required in order to suppress the protic dissociation of the co-ordinated amine groups. On increasing the $\mathrm{HClO}_{4}$ concentration the absorption maximum at 314 nm first moved to higher wavelengths [until curve (b) was obtained] and then moved slightly towards lower wavelengths with further increase in the absorption coefficient [curves (c) and (d)]. The initial change, $(a)$ to $(b)$, is associated mainly with shifts in the equilibrium (2). Under the experimental conditions of
$[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+}(\mathrm{I}) \stackrel{K\left[\mathrm{H}^{+}\right]\left[\mathrm{Cl}^{-}\right]}{\rightleftharpoons}$

$$
\begin{equation*}
\left[\mathrm{AuCl}_{2}(3 \mathrm{NMe}-\mathrm{Hpd})\right]^{2+}(\mathrm{II}) \tag{2}
\end{equation*}
$$

curve (b) $\left(\left[\mathrm{HClO}_{4}\right]=0.3 \mathrm{~mol} \mathrm{dm}^{-3}\right)$ complex (I) has almost disappeared; (II), however, is not the only other species present since also $\left[\mathrm{AuCl}_{3}(3 \mathrm{NMe}-\mathrm{Hpd})\right]^{+}$, (IIII), and $\left[\mathrm{AuCl}_{3}-\right.$ ( $3 \mathrm{NMe}-\mathrm{H}_{2} \mathrm{pd}$ ) $]^{2+}$, (IV), with unidentate ligand, are formed to some extent [approximate composition of the equilibrium mixture in (b) is: (I), 4; (II), 68; (III), 2; (IV), 26\%]. The spectral changes (b) to (c) to (d) are associated with shifts in the equilibria (3) [approximate composition of the

$$
\left.\begin{array}{r}
{\left[\mathrm{AuCl}_{2}(3 \mathrm{NMe}-\mathrm{Hpd})\right]^{2+}(\mathrm{II}) \stackrel{K_{1}\left[\mathrm{Cl}^{-}\right]}{\rightleftharpoons}\left[\mathrm{AuCl}_{3}(3 \mathrm{NMe}-\mathrm{Hpd})\right]^{+}(\mathrm{III})} \\
\stackrel{\left.K_{8} \mathrm{H}+\right]}{\rightleftharpoons}
\end{array} \mathrm{AuCl}_{3}\left(3 \mathrm{NMe}^{2}-\mathrm{H}_{2} \mathrm{Pd}\right)\right]^{+}(\mathrm{IV}) \quad \text { (3) }
$$

equilibrium mixtures in (c) and (d) are: (I) 1 , (II) 43, (III) 1.5, (IV) 54.5; and (I) 0.5 , (II) 34 , (III) 1 , (IV) $64.5 \%$
respectively]. It is to be noted that under the experimental conditions of curves (c) and (d) the reaction [ $\mathrm{AuCl}_{3}(3 \mathrm{NMe}-$ $\left.\left.\mathrm{H}_{2} \mathrm{Pd}\right)\right]^{2+} \longrightarrow\left[\mathrm{AuCl}_{4}\right]^{-}$takes place causing the spectral changes (1)-(3) shown in Figure 1. Near 280 nm the changes in absorbance are mainly caused by shifts in equilibrium (2) and it is possible, by measuring the absorbance as a function of $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]$(see Experimental section), to evaluate $K$ which is found to be $c a .3 \times 10^{3} \mathrm{dm}^{6}$ $\mathrm{mol}^{-2}$.

Similar behaviour was observed for the $[\mathrm{AuCl}(3 \mathrm{NH}-\mathrm{pd})]^{2+}$ complex but, because of unfavourable spectral conditions,

Figure 1 Absorption spectrum of $3.5 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$ [AuCl$(3 \mathrm{NMe}-\mathrm{pd})]^{2+}$ in $5 \% \mathrm{v} / \mathrm{v}$ water-methanol and $I=1.7 \mathrm{~mol} \mathrm{dm}^{-3}$, $\left.\left(\mathrm{Li}_{[\mathrm{ClO}}^{4} \mathrm{]}\right]\right) ;[\mathrm{Cl}]=1.82 \times 10^{-2} \mathrm{~mol} \mathrm{dm}{ }^{-3} ;\left[\mathrm{H}^{+}\right]=10^{-3}(a)$ $0.3(b), 1.0(c)$, and $1.5 \mathrm{~mol} \mathrm{dm}^{-3}(d)$. Spectral changes (1)-(3) of (c) and (d) are associated with the reaction: $\left[\mathrm{AuCl}_{3}(3 \mathrm{NMe}-\right.$ $\left.\left.\mathrm{H}_{2} \mathrm{Pd}\right)\right]^{2+}+\mathrm{Cl}^{-}+\mathrm{H}^{+} \longrightarrow\left[\mathrm{AuCl}_{4}\right]^{-}+\left[3 \mathrm{NMe}^{-} \mathrm{H}_{3} \mathrm{Pd}\right]^{3+}$
the constant of equilibrium (4) can only be estimated as $\geqslant 10^{4} \mathrm{dm}^{6} \mathrm{~mol}^{-2}$.

$$
[\mathrm{AuCl}(3 \mathrm{NH}-\mathrm{pd})]^{2+} \stackrel{K\left[\mathrm{H}^{+}\right]\left[\mathrm{Cl}^{-}\right]}{\sim}\left[\mathrm{AuCl}_{2}(3 \mathrm{NH}-\mathrm{Hpd})\right]^{2+}
$$

In both cases, under the experimental conditions of the kinetic runs, equilibrium (2) can be considered as completely shifted to the right. The spectroscopic course of the displacement reaction is shown in Figure 2 for $3 \mathrm{NMe}-\mathrm{pd}$. The presence of a well defined isosbestic point right from the beginning clearly indicates that the reaction occurs in a single step. The wavelength at which the isosbestic point occurs was not the same in different runs since the composition of the equilibrium mixture of (II)-(IV) varies as a function of $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]$. The final spectrum showed a peak at 317 nm which corresponds, apart from a small contribution from the ligand, to that of $\left[\mathrm{AuCl}_{4}\right]^{-} .{ }^{13}$

Reaction of Displacement of 3NH-pd.-The observed rate constants are given in Table 1. At a given chloride concentration the reaction rate tended to a limiting value as the acid concentration was increased, and the reciprocal of the rate constant was a linear function of the reciprocal of the acid concentration. These results are in accord with expression (5), where $B_{0}$ and $B_{1}$ are respectively the intercept
${ }^{13}$ H. B. Gray and C. J. Ballhausen, J. Amer. Chem. Soc., 1963, 85, 260 ; A. K. Gongopadhayay and A. Chakravorty, J. Chem. Phys., 1961, 35, 2206.
and gradient of the linear plot of $1 / k_{\text {obs. }}$ against $1 /\left[\mathrm{H}^{+}\right]$at constant [ $\mathrm{Cl}^{-}$]. Their values, calculated by least-squares fit, are given in Table 2.

$$
\begin{equation*}
k_{\mathrm{obs},}=\left[\mathrm{H}^{+}\right] /\left(B_{0}\left[\mathrm{H}^{+}\right]+B_{1}\right) \tag{5}
\end{equation*}
$$

These parameters depend on the concentration of chloride. A plot of $1 / \mathrm{B}_{0}$ against $\left[\mathrm{Cl}^{-}\right]$was linear and passed

Figure 2 Spectroscopic course of the reaction [AuCl$(3 \mathrm{NMe}-\mathrm{pd})]^{2+}+3 \mathrm{Cl}^{-}+3 \mathrm{H}^{+} \longrightarrow\left[\mathrm{AuCl}_{4}\right]^{-}+[3 \mathrm{NMe}-$
$\left.\mathrm{H}_{3} \mathrm{pd}\right]^{3+}$. $\left[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})^{2+}\right]_{0}=10^{-4},\left[\mathrm{H}^{+}\right]=0.363,\left[\mathrm{Cl}^{-}\right]=$ $2.82 \times 10^{-2}, I=1.7 \mathrm{~mol} \mathrm{dm}{ }^{-3}\left(\mathrm{Li}^{2}\left[\mathrm{ClO}_{4}\right]\right), 25{ }^{\circ} \mathrm{C}$. Curves (0)-(5) show spectra at zero time and after $15,36,70,120$, and 300 min respectively
through the origin (Figure 3). The gradient $[1 / \gamma$ in equation (6)] is ( $4.47 \pm 0.14) \times 10^{-2} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$. Also, $B_{1}$ decreased as $\left[\mathrm{Cl}^{-}\right]$increased but with a more complex dependence than $B_{0}$. A plot of $B_{1}\left[\mathrm{Cl}^{-}\right]$against $1 /\left[\mathrm{Cl}^{-}\right]$

$$
\begin{equation*}
B_{0}=r /\left[\mathrm{Cl}^{-}\right] \tag{6}
\end{equation*}
$$

(Figure 4) gave a straight line with intercept $t=0.89 \pm$ $0.13 \mathrm{~mol}^{2} \mathrm{dm}^{-6} \mathrm{~s}$ and gradient $s=0.38 \pm 0.01 \mathrm{~mol}^{3} \mathrm{dm}^{-9} \mathrm{~s}$,

Figure 3 Dependence of $1 / B_{0}$ (see text) on [ $\left.\mathrm{Cl}^{-}\right]$. Circles and squares refer to the reactions $[\mathrm{AuCl}(3 \mathrm{NH}-\mathrm{pd})]^{2+}+3 \mathrm{Cl}^{-}+$ $3 \mathrm{H}^{+} \longrightarrow\left[\mathrm{AuCl}_{4}\right]^{-}+\left[3 \mathrm{NH}-\mathrm{H}_{3} \mathrm{pd}\right]^{3+}$ and $[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+}$ $+3 \mathrm{Cl}^{-}+3 \mathrm{H}^{+} \longrightarrow\left[\mathrm{AuCl}_{4}\right]^{-}+\left[3 \mathrm{NMe}-\mathrm{H}_{3} \mathrm{pd}\right]^{3+}$ respectively
indicating that the dependence of $B_{1}$ on chloride has the form (7).

$$
\begin{equation*}
B_{\mathbf{1}}=\left(s+t\left[\mathrm{Cl}^{-}\right]\right) /\left[\mathrm{Cl}^{-}\right]^{2} \tag{7}
\end{equation*}
$$

From equations (5)-(7) we can write expression (8) for the overall dependence of $k_{\text {obs. }}$ on $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]$.

$$
\begin{equation*}
k_{\text {obs. }}=\left[\mathrm{H}^{+}\right]\left[\mathrm{Cl}^{-}\right]^{2} /\left(r\left[\mathrm{Cl}^{-}\right]\left[\mathrm{H}^{+}\right]+s+t\left[\mathrm{Cl}^{-}\right]\right) \tag{8}
\end{equation*}
$$

Reaction of Displacement of $3 N M e-p d$.-The observed rate constants are given in Table 3. A plot of the reciprocal of the rate constant against the reciprocal of the hydrogen-ion concentration was also linear and the $B_{0}$ and $B_{1}$ parameters [equation (5)] obtained by least-squares fit are given in Table 4. The dependence of $B_{0}$ on [ $\mathrm{Cl}^{-}$] was determined by plotting the reciprocal of $B_{0}$ against the chloride concentration; a straight line with zero intercept and gradient $1 / r$ [equation (6), Figure 3] was obtained; the value of $1 / r$ is $(1.77 \pm 0.27) \times 10^{-2} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$. The dependence of $B_{1}$ on $\left[\mathrm{Cl}^{-}\right]$is also analogous to that found with the $3 \mathrm{NH}-\mathrm{pd}$ derivative [equation (7), Figure 4]; values of $t$ and $s$

Figure 4 Dependence of $B_{1}\left[\mathrm{Cl}^{-}\right]$on $1 /\left[\mathrm{Cl}^{-}\right]$. For key see Figure 3
estimated from the plot of $B_{1}\left[\mathrm{Cl}^{-}\right]$against $1 /\left[\mathrm{Cl}^{-}\right]$are $1.56 \pm 0.98 \mathrm{~mol}^{2} \mathrm{dm}^{-6} \mathrm{~s}$ and $0.82 \pm 0.31 \mathrm{~mol}^{3} \mathrm{dm}^{-9} \mathrm{~s}$ respectively.

Deprotonation of Co-ordinated $3 N M e-p d$.-The $\mathrm{p} K_{\mathrm{a}}$ of equilibrium (9) in $0.5 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}\left[\mathrm{ClO}_{4}\right]$ and in $0.5 \mathrm{~mol} \mathrm{dm}^{-3}$
$[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+} \xlongequal{K_{\mathrm{a}}}[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd}-\mathrm{H})]^{+}+\mathrm{H}^{+}(9)$
NaCl was determined. A potentiometric titration of $[\mathrm{AuCl}(3 \mathrm{NMe}-\mathrm{pd})]^{2+}$ with sodium hydroxide gave a distinct end-point after the addition of exactly one equivalent of base per mole of substrate. During the titration the colour of the solution changed from yellow to reddish brown and the pH rose above 7 at the equivalence point. Further addition of base did not cause a sharp increase in pH and no further distinct end-points could be detected. As observed for analogous gold complexes, reduction ${ }^{7}$ or the formation of other amido-species probably occurs. ${ }^{14}$ The determined $\mathrm{p} K_{\mathrm{a}}$ values are $5.7 \pm 0.1$ in $0.5 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}\left[\mathrm{ClO}_{4}\right]$ and $6.8 \pm 0.1$ in $0.5 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaCl}$.

[^1]
## discussion

The experimentally determined rate equation is completely analogous to that found in the displacement of teen and tmen from $\left[\mathrm{AuCl}_{2}(\mathrm{~N}-\mathrm{N})\right]^{+}$complexes and a similar mechanism can therefore be invoked. The equilibrium $(\mathrm{I}) \rightleftharpoons(\mathrm{II})$ is completely shifted to the
from their $\left[\mathrm{AuCl}_{2}(\mathrm{~N}-\mathrm{N})\right]^{+}$complexes; in the light of the present results, however, equation (10) would seem to be more appropriate and in the following discussion a direct comparison between the displacement of tridentate ( 3 NH - or $3 \mathrm{NMe}-\mathrm{pd}$ ) and bidentate ligands (teen or tmen) will be made.

(I)
(II)
(III)

(I)
(IV)
right under the experimental conditions of the kinetic runs and it therefore does not influence the reaction rate. There is direct spectroscopic evidence that species (II)(IV) are in equilibrium and, making this assumption, equation (10) may be deduced for the observed rate constant. A direct step (III) $\longrightarrow(\mathrm{V})$ has been ruled
$k_{\text {obs. }}=\frac{\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right)\left(k_{3}+k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{2}\left[\mathrm{H}^{+}\right]}{k_{-1} k_{-2}+\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{-2}{ }^{\prime}{ }^{\prime}\left(\mathrm{Cl}^{-}\right) k_{2}\left[\mathrm{H}^{+}\right]}$
$+\left(k_{1}+k_{1}\left[\mathrm{l}^{\prime}\right]\right.$
out since in this case an additional term independent of [ $\mathrm{H}^{+}$] would appear in the numerator of expression (10), and under these circumstances the observed rate constant would not tend to zero (as observed) as the hydrogen-ion concentration tended to zero. Steps (II) $\rightarrow$ (III) and (IV) $\rightarrow$ (V) have been written in the general form for substitution reactions in square-planar complexes, although it will be seen later that $k_{1}$ and $k_{3}$ are not detectable.

If the steady-state approximation, instead of pre-equilibrium, is made for species (III) and (IV) equation (ll) is obtained for the rate constant. In

$$
\begin{array}{r}
k_{\text {obs. }}=\frac{\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right)\left(k_{3}+k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{2}\left[\mathrm{H}^{+}\right]}{k_{-1} k_{-2}+\left(k_{3}+k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{3}-1}  \tag{11}\\
+\left(k_{3}+k_{3}{ }^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{2}\left[\mathrm{H}^{+}\right]
\end{array}
$$

equations ( 10 ) and ( $\mathbf{1 1}$ ) the dependence of $k_{\text {obs. }}$ on $\left[\mathrm{H}^{+}\right]$ and $\left[\mathrm{Cl}^{-}\right]$is formally the same and both expressions are in accord with the experimental rate equation; however, not all the kinetic constants which appear in the denominators of (10) and (11) are the same. Equation (11) was adopted in the interpretation of the kinetic data for the displacement of the bidentate ligands teen and tmen

From equations (5) and (10) expressions (12) and (13) may be obtained for $B_{0}$ and $B_{1}$ respectively. The observation that $B_{0}$ is inversely proportional to $\left[\mathrm{Cl}^{-}\right]$indicates that $k_{3}$ is extremely small and its contribution to

$$
\begin{gather*}
B_{0}=\left(k_{3}+k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]\right)^{-1}  \tag{12}\\
B_{1}=\frac{k_{-1} k_{-2}+\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{-2}}{\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right)\left(k_{3}+k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{2}} \tag{13}
\end{gather*}
$$

the reaction rate is insignificant. Assuming $k_{3}=0$ equation (13) can be rewritten as (14), and a plot of $1 / B_{1}\left[\mathrm{Cl}^{-}\right]$against $\left[\mathrm{Cl}^{-}\right]$should give a curve with intercept (at $\left.\left[\mathrm{Cl}^{-}\right]=0\right) k_{1} k_{3}^{\prime} k_{2} /\left(k_{-1} k_{-2}+k_{1} k_{-2}\right)$ and approaching a limiting value as the chloride concentration increases.

$$
\begin{equation*}
\frac{1}{B_{1}\left[\mathrm{Cl}^{-}\right]}=\frac{\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{3}{ }^{\prime} k_{2}}{k_{-1} k_{-2}+\left(k_{1}+k_{1}^{\prime}\left[\mathrm{Cl}^{-}\right]\right) k_{-2}} \tag{14}
\end{equation*}
$$

Since this intercept appeared to be zero, we can assume that $k_{1}$ is also insignificant compared with $k_{1}\left[\mathrm{Cl}^{-}\right]$. Assuming $k_{1}=0$, equation (14) gives (15) and a plot of $\left.B_{1} \mathrm{Cl}^{-}\right]$against $1 /\left[\mathrm{Cl}^{-}\right]$should be a straight line (as is actually observed) with gradient $s=k_{-1} k_{-2} / k_{1} k_{2} k_{3}{ }^{\prime}$ and

$$
\begin{equation*}
B_{1}\left[\mathrm{Cl}^{-}\right]=\frac{k_{-1} k_{-2}+k_{1}{ }^{\prime} k_{-2}\left[\mathrm{Cl}^{-}\right]}{k_{1}{ }^{\prime} k_{2} k_{3}^{\prime}\left[\mathrm{Cl}^{-}\right]} \tag{15}
\end{equation*}
$$

intercept $t=k_{-2} / k_{2} k_{3}{ }^{\prime}$. From the values of $r, s$, and $t$ the kinetic constant $k_{3}^{\prime}=1 / r$ and the equilibrium constants $k_{1}^{\prime} / k_{-1}=K_{1}=t / s$ and $k_{2} / k_{-2}=K_{2}=r / t$ were calculated (Table 5). The analogous constants calculated from the values of $r, s$, and $t$ for the complexes $\left[\mathrm{AuCl}_{2}-\right.$ (teen) $]^{+}$and $\left[\mathrm{AuCl}_{2}(\text { tmen })\right]^{+}$are also included in Table 5 .

The $k_{3}{ }^{\prime}$ values of the complexes (Table 5) do not change significantly on going from 3 NMe -pd to $3 \mathrm{NH}-\mathrm{pd}$ and
from teen to tmen; however, the constants are about ten times smaller for the tridentate ligands than for the bidentate ones. This difference can be related to the different nature of the donor group which is a primary

Complex

| $\frac{10^{2} k_{3}^{\prime}}{}$ | $\frac{\left(k_{1}{ }^{\prime} / k_{-2}\right)}{\mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}}$ | $\frac{\left(k_{2} / k_{-2}\right)}{\mathrm{dm}^{3} \mathrm{~mol}^{-1}}$ |
| :--- | :--- | :--- |

amine in $3 \mathrm{NH}-\mathrm{pd}$ and $3 \mathrm{NMe}-\mathrm{pd}$ and a tertiary amine in teen and tmen. Considering the basicity of the groups displaced in this step $\left[\mathrm{Et}_{2}(\mathrm{H}) \stackrel{+}{\mathrm{N}} \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot \mathrm{NEt}_{2}, \mathrm{Me}_{2}-\right.$ (H) $\stackrel{+}{\mathrm{N}} \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot \mathrm{NMe}_{2}, \quad \mathrm{H}_{3} \stackrel{+}{\mathrm{N}} \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot \stackrel{+}{\mathrm{N}}\left(\mathrm{H}_{2}\right) \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot$ $\mathrm{NH}_{2}$, and $\left.\mathrm{H}_{3} \stackrel{+}{\mathrm{N}} \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot \stackrel{+}{\mathrm{N}} \mathrm{Me}(\mathrm{H}) \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot \mathrm{NH}_{2}\right]$ one finds that $\log K_{\mathrm{b}}$ of the first two amines is 6.45 and 5.94 respectively; ${ }^{15}$ the corresponding values for the last two amines cannot be measured (the terminal nitrogen atom is more basic than the central one), but should not be much different from that of $\mathrm{H}_{3} \stackrel{+}{\mathrm{N}} \cdot \mathrm{CH}_{2} \cdot \mathrm{CH}_{2} \cdot \mathrm{NH}_{2}$ which is 7.47. ${ }^{16}$ In addition to the effect of basicity, the higher steric hindrance of the tertiary amines, when compared to that of primary amines, could also be the cause of their higher reactivity. The values of $k_{3}{ }^{\prime}$ can be compared with the rate constant for displacement of nitrogen bases (am) from complexes of the type $\left[\mathrm{AuCl}_{3}(\mathrm{am})\right],{ }^{17}$ and, as expected, they fall in the same range.

The equilibrium constants, $K_{1}=k_{1}^{\prime} \mid k_{-1}$, are of the same order of magnitude in the present complexes and their values indicate that the equilibrium between the uni- and bi-dentate forms of the ligand is not greatly shifted in favour of one of the two species. This result would appear to be in contrast with the well known chelate effect; ${ }^{18}$ however we are dealing with rather peculiar ligands. The ligands teen and tmen have tertiary amine groups and it has been already shown that on increasing the N -alkyl substitution the rate of reformation of the second bond $\left(k_{-1}\right)$ decreases and that of bond rupture ( $k_{1}{ }^{\prime}$ ) slightly increases. ${ }^{15}$ Apparently, teen does not co-ordinate to $\mathrm{Ni}^{\text {II }}$ and evidence for the unidentate behaviour of NN -diethylethylenediamine towards the same metal ion has been produced. Moreover, in the reaction of tmen with $\mathrm{Ni}^{\mathrm{II}}$ the ring-closing and ring-opening rates were found to differ only by one order of magnitude. The same steric arguments apply to the complexes of 3 NMe -pd and, to some extent, to those of 3 NH-pd. In addition, the presence in the latter cases of one adjacent protonated amine group [see intermediate

[^2](II) in the reaction scheme], lowering the basicity of the co-ordinated nitrogen, enhances the $k_{1}^{\prime}$ value.

The equilibrium constant for protonation of the free end of the polydentate ligand, (III) $\rightleftharpoons$ (IV), is $K_{2}=$ $k_{2} / k_{-2}$. The calculated values of $K_{2}$ (Table 5) fall in the same range for all the complexes considered here and are much smaller than those measured for the unco-ordinated ligands (log $K_{\mathrm{b}}$ for [Hteen $]^{+}$, [Htmen] ${ }^{+}$, $\left[3 \mathrm{NH}-\mathrm{H}_{2} \mathrm{pd}\right]^{2+}$, and $\left[3 \mathrm{NMe}-\mathrm{H}_{2} \mathrm{pd}\right]^{2+}$ are $6.45,5.94,4.6$, and 3.1 respectively ${ }^{15,19}$ ). Among other factors, this could be due to the greater steric hindrance exerted by the metallic residue when compared with that of a proton.
In the reaction scheme we have assumed that in step (II) $\rightarrow$ (III) the central nitrogen atom, and not the terminal one, is displaced from the metal. In the terminal case we would expect: (i) $k_{3}$ ' of the same magnitude in the four complexes; (ii) $K_{1}$ larger in the teen and tmen complexes than in those of $3 \mathrm{NH}-\mathrm{pd}$ and $3 \mathrm{NMe}-\mathrm{pd}$; and (iii) $K_{2}$ larger in the $3 \mathrm{NH}-\mathrm{pd}$ and $3 \mathrm{NMe}-\mathrm{pd}$ complexes than in those of teen and tmen. All three conclusions are in contrast with the experimental results, which support the assumption that the central nitrogen is displaced first.

So far we have discussed the behaviour of the triamine complexes of $\mathrm{Au}^{\mathrm{III}}$ in highly acidic chloride solutions. For completeness we must say that in less acidic media deprotonation of the co-ordinated amine occurs. Data concerning the deprotonation of $3 \mathrm{NH}-\mathrm{pd}$ in $[\mathrm{AuCl}(3 \mathrm{NH}-$ $\mathrm{pd})]^{2+}$ have been reported by Baddley et al. ${ }^{9}$; we have measured the equilibrium constant for deprotonation of $3 \mathrm{NMe}-\mathrm{pd}$ in the analogous complex. In Table 6 the

${ }^{a}$ B. P. Block and J. C. Bailar, jun., J. Amer. Chem. Soc., 1951, 73, 4722. ${ }^{b}$ This work.
$\mathrm{p} K_{\mathrm{a}}$ values of different co-ordinated amines are compared. It appears that the major differences in these values occur between the different types of acidic nitrogens; in particular on going from primary to secondary nitrogen atoms the $\mathrm{p} K_{\mathrm{a}}$ increases by approximately two units. This comparison must be made between data obtained under the same conditions since an anomalous enhancement of $\mathrm{p} K_{\mathrm{a}}$ was observed in the presence of coordinating ions. ${ }^{20}$
