## Crystal and Molecular Structure of Methyltriphenylphosphonium Hexaiodotetracuprate(1)

By Graham A. Bowmaker, George R. Clark,* and D. K. Paul Yuen, Department of Chemistry, University of Auckland, Auckland, New Zealand

#### Abstract

The crystal structure of the title compound has been determined from single-crystal $X$-ray diffraction data by conventional methods. The yellow complex crystallises in rhombohedral space group $R \overline{3} c$, with $Z=2$ in unit cell of dimensions $a=b=c=15.603(2) A, \alpha=\beta=\gamma=53.133(2)^{\circ}$. Full-matrix least-squares refinement returned a final $R$ factor of 0.038 for 1206 reflections. The complex has overall $C_{3 v}$ symmetry, with the $\left[\mathrm{Ph}_{3} \mathrm{MeP}\right]+$ ion adopting a ' propeller-like ' conformation and the $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ion forming a tetrahedron of copper atoms with iodine atoms displaced from the centre of each edge. Thus each copper atom has approximately trigonal planar co-ordination and is bridged by three iodine atoms. Within the crystal alternate anions have an inverted core of copper atoms whilst still accommodating the same iodine atoms on tetrahedron edges. Cu-l bond distances range from 2.539(5) to $2.638(5) \AA$, and $\mathrm{Cu}-1-\mathrm{Cu}$ bond angles are $63.9(2)$ and $65.2(2)^{\circ}$. The non-bonded $\mathrm{Cu} \cdots \mathrm{Cu}$ separations of the $\mathrm{Cu}_{4}$ tetrahedron are $2.742(7)$ and 2.757 (7) $A$. Tine observed structure is consistent with that previously suggested on the basis of i.r., Raman, and n.q.r. studies.

Halogenocuprate(i) complexes exhibit a wide variety of stoicheiometries, with structures mainly based upon a tetrahedral copper co-ordination; e.g., $\left[\mathrm{CuCl}\left(\mathrm{PPh}_{3}\right)_{3}\right]$ and $\left[\mathrm{CuCl}(\mathrm{dmt})_{3}\right]$ (dmt $=$ dimethylthiourea) are mononuclear, ${ }^{1,2}\left[(\mathrm{CuCl})_{2}\left(\mathrm{PPh}_{3}\right)_{3}\right]$ and $\left[(\mathrm{CuCl})_{2}(\mathrm{cot})_{3}\right] \quad(\mathrm{cot}=$ trans-cyclo-octene) are dinuclear, ${ }^{3,4} \mathrm{~K}_{2}\left[\mathrm{CuCl}_{3}\right],\left[\mathrm{NH}_{4}\right]_{2}-$ $\left[\mathrm{CuCl}_{3}\right]$, and $\left[\mathrm{NH}_{4}\right]_{2}\left[\mathrm{CuBr}_{3}\right]$ have $\mathrm{CuX}_{4}$ groups sharing two corners to form infinite $\left[\mathrm{CuX}_{3}\right]_{n}^{2 n-}$ polymers, ${ }^{5,6}$ and $\mathrm{Cs}\left[\mathrm{Cu}_{2} \mathrm{Cl}_{3}\right]$ and $\left[\mathrm{PhN}_{2}\right] \mathrm{Cu}_{2} \mathrm{Br}_{3}$ form double chains of $\left[\mathrm{Cu}_{2} \mathrm{X}_{3}\right]_{n}{ }^{n-}$ ions. ${ }^{7,8}$

Recently $X$-ray crystal structure determinations have established some unusual geometries, e.g. the complex

[^0]$\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6-4}\right]_{4}\left[\mathrm{Cu}_{5} \mathrm{Cl}_{17}\right]$ contains the $\left[\mathrm{Cu}_{5} \mathrm{Cl}_{16}\right]^{11-}$ ion in which four $\mathrm{CuCl}_{4}$ tetrahedra share a chlorine atom with a central tetrahedral $\mathrm{Cu}^{+}$ion. ${ }^{9}$ Of particular interest are the complexes of general formula $\left[(\mathrm{CuX})_{n} \mathrm{~L}_{m}\right]$, where L is a neutral ligand, which have been found to adopt the 'cubane' (copper atoms all four-co-ordinate tetrahedral) ${ }^{10-12}$ or 'step' (two copper atoms four-co-ordinate tetrahedral, two three-co-ordinate trigonal) ${ }^{13-16}$ structures.
Bowmaker et al. have recently synthesised compounds containing the anion $\left[\mathrm{CuX}_{2}\right]^{-}(\mathrm{X}=\mathrm{Cl} \text { or } \mathrm{Br})^{17}$ but when attempting to prepare $\left[\mathrm{CuI}_{2}\right]^{-}$they obtained a bright

yellow crystalline ionic solid which analysed as $\left(\mathrm{Ph}_{3}-\right.$ $\mathrm{MeP}) \mathrm{Cu}_{2} \mathrm{I}_{3}$. The colour suggested a multinuclear anion; i.r., Raman, and n.q.r. spectra were consistent with the presence of the hexaiodotetracuprate( I ) ion $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$, and a structure was suggested in which the copper atoms lie on the corners of a tetrahedron with iodine atoms bridging along the edges, to give each copper atom a trigonal co-ordination. ${ }^{18}$ We have investigated the crystal structure in an attempt to confirm the existence of the $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ion and to provide further data relative to trigonal copper co-ordination.

## EXPERIMENTAL

The crystals are thick yellow needles with hexagonal cross-section. Initial $X$-ray photography showed the crystals to be rhombohedral, the (111) direction coinciding with the needle elongation. Unit-cell constants were determined from a least-squares refinement of the setting angles of twelve high-angle reflections ( $\theta$ range $16.3-20.5^{\circ}$ ) by use of a Hilger and Watts four-circle automatic diffractometer. ${ }^{19}$

Crystal Data.- $\mathrm{C}_{38} \mathrm{H}_{36} \mathrm{Cu}_{4} \mathrm{I}_{6} \mathrm{P}_{2}, \quad M=1570.2$, Rhombohedral, $a=b=c=15.603(2) \AA, \alpha=\beta=\gamma=53.133(2)^{\circ}$ (standard deviations from the least-squares fitting to the setting angles), $U=2253.7 \AA^{3}, D_{\mathrm{m}}=2.33 \mathrm{~g} \mathrm{~cm}^{-3}, Z=2$, $D_{\mathrm{c}}=2.31 \mathrm{~g} \mathrm{~cm}^{-3}, \quad F(000)=1456$. Mo- $K_{\alpha}$ radiation, $\lambda=0.7107 \AA, \mathrm{Zr}$ filter; $\mu\left(\mathrm{Mo}-K_{\alpha}\right)=54.3 \mathrm{~cm}^{-1}$. Space group $R \overline{3} c$ (No. 167). Crystal size $0.23 \times 0.17 \times 0.17 \mathrm{~mm}$, crystal faces $\{111\},\{011\}$; mosaic spread $0.12^{\circ}$.

Intensity data within a Bragg limit of $27^{\circ}(\sin \theta / \lambda 0.64)$ were collected by an asymmetric $2 \theta-\omega$ scan of 65 steps from $0.50^{\circ}$ in 20 below, to $0.80^{\circ}$ in 20 above the calculated $K_{\bar{\alpha}}$ peak position. Each step was counted for 2 s , with 30 s stationary-background counts at each end of the scan range. Reflections examined were $\pm h, \pm k, \pm l$ with the restriction $l \geqslant k \geqslant h$ giving two independent measurements for each equivalent reflection. These were averaged to give 1206 unique reflections with $I>3 \sigma(I)$ [where $\sigma(I)=\{T+$ $\left.t^{2} B+(p I)^{2}\right\}^{\sharp}, T=$ integrated peak count, $B=$ average background count, $t=$ ratio of scan to background times, $p$ was assigned a value of 0.04$].{ }^{20 a}$ Data were corrected for Lorentz and polarisation factors and for absorption. ${ }^{20 b}$

Structure Determination and Refinement.-The entire unit cell contains $12 \mathrm{I}, 8 \mathrm{Cu}, 4 \mathrm{P}, 4$ methyl, and 12 phenyl groups. The general multiplicity of space group $R \overline{3} c$ is 12 and therefore most of the atoms are required to occupy special positions. ${ }^{21}$ The P atoms must occupy ( $a$ ) and (b), or (c); the methyl group must occupy (a) and (b), or (c): the Cu atoms could occupy (a) and (d), or (a) and (e), or (b) and (d), or $(b)$ and $(e)$, or $(a)$ and $(b)$ and (c), or else two sets of 4 in positions (c); the I and phenyl groups could be in general positions ( $f$ ) or some combinations of the special positions. As the heaviest atoms, iodine, were in fact the least-rigidly constrained, a Patterson function was computed and the iodine atoms were located and found to occupy general positions. It was expected that the copper-atom positions would be readily deduced by examination of the Patterson function for I ... Cu vectors, but surprisingly, no copper atom positions could be found which were fully consistent with their restricted positions and the expected peak heights in the Patterson synthesis. An electron-density synthesis
${ }^{18}$ G. A. Bowmaker, L. D. Brockliss, C. D. Earp, and R. Whiting, Austral. J. Chem., 1973, 26, 2593.
${ }^{19}$ W. R. Busing and H. A. Levy, Acta Cryst., 1967, 22, 457.
phased by the I atom alone was therefore computed. This revealed two large peaks in positions (c) with $x=0.04$ and 0.17 , and another solitary peak of nearly similar height in a completely general position. These 12 'atoms' corresponding to the peak in the general position occurred in pairs separated by only $1.8 \AA$, and it was evident that the emerging structure did not match the expected molecular geometry nor even the atomic composition analysis. Nevertheless, the two larger peaks were assigned scattering factors appropriate to copper and the other peak those appropriate to phosphorus. A structure-factor calculation was then computed. This lowered the residual $R$ from 0.54 (I only) to 0.20 . Trial least-squares cycles were computed, including refinement of occupancy factors and isotropic temperature factors. In this way $R$ was reduced to 0.169 . The results of these refinements are listed in Table 1.

Table 1

|  | Attempted refinement of trial model |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Initial | Refined | Initial | Refined |  |  |  |
| Atoms | $B$ | $B$ | occupancy | occupancy |  |  |  |
| I | 3.6 | 3.5 | 1.00 | $1.00{ }^{*}$ |  |  |  |
| $\mathrm{Cu}(\mathbf{1})$ | 4.5 | 6.6 | 0.33 | 0.18 |  |  |  |
| $\mathrm{Cu}(2)$ | 4.5 | 6.8 | 0.33 | 0.10 |  |  |  |
| P | 4.5 | 1.4 | 1.00 | 1.12 |  |  |  |
|  | * Not refined. |  |  |  |  |  |  |

The atoms labelled $\mathrm{Cu}(1)$ and $\mathrm{Cu}(2)$ should clearly be lighter atoms than Cu , that labelled P should actually be heavier than P. The refined occupancy factor of the atom labelled $\mathrm{Cu}(\mathrm{I})$ is approximately one half of its initial value. Once the possibility of half-weighting or 'systematic disorder' was conceived the true atomic arrangement quickly became apparent: I occupied 12 general positions, Cu two independent copper atoms, four half-weighted Cu atoms on (c) i.e. $x, x, x$, at $x=0.04$, and twelve half-weighted Cu atoms in general positions. Thus total Cu atoms in cell $=$ $4 \times \frac{1}{2}+12 \times \frac{1}{2}=8 ; \mathrm{P}-4 \mathrm{P}$ atoms on (c) at $x=0.17$.
This is consistent with the analysis figures, the n.q.r. results which indicated two kinds of copper atoms present in a 1:3 ratio, the likely molecular geometry, the Patterson peak-heights and distribution, and the attempted refinement results.

The existence of the half-weighted Cu atoms can be rationalised in the following way. The Cu atoms form a tetrahedral pattern in which one Cu atom lies on the threefold axis and three Cu atoms are positioned symmetrically about the axis. The iodine atoms occupy the edges of the tetrahedron, giving a basic anionic unit $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$. Every alternate $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ion has its $\mathrm{Cu}_{4}$ tetrahedron inverted, but still accommodates the same I atoms on its tetrahedron edges. Any individual tetrahedron has its full complement of atoms, but time-averaging causes the copper atoms to appear half-weighted. The close approach (1.8 $\AA$ ) referred to earlier does not in reality occur, as the atoms involved alternate from one unit to the next.
The appropriate changes were made to the atom labels, form-factor identifiers, and occupancies, and a structurefactor calculation then returned a reliability index $R$ of

0.166. A difference-Fourier now clearly revealed the methyl carbon atom and all carbon positions of the benzene ring.

Full-matrix least-squares refinement was then commenced. ${ }^{22}$ Atomic scattering factors were from ref. 23,

with those for iodine and copper corrected for real dispersion effects. ${ }^{24}$ The function minimised was $\Sigma v\left(\left|F_{0}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$,

Their packing into the unit cell is displayed in Figure 1. To avoid confusion only one anion (in only one of the two possible configurations) and its encompassing array of phosphine cations has been drawn. The omitted anions are located about each corner of the rhombohedron. Observed bond distances and angles are listed in Tables 4 and 5 respectively.

The Methyltriphenylphosphonium Cation.-The $\left[\mathrm{Ph}_{3}-\right.$ $\mathrm{MeP}]^{+}$ion has an overall geometry which resembles a propeller, similar to those observed in other complexes containing this ion. ${ }^{26-30}$ In the present compound, crystallographic symmetry demands a regular twist of the propeller ' blades ', the angle of twist, as defined by the $\mathrm{C}(\mathrm{Me})-\mathrm{P}-\mathrm{C}(\mathrm{I})-\mathrm{C}(6)$ torsion angle, being $-54^{\circ}$. This geometry, together with the numbering scheme and bond lengths and angles, is depicted in Figure 2.

The phosphorus atom is tetrahedral $[\mathrm{C}(\mathrm{Me})-\mathrm{P}-\mathrm{C}(\mathbf{l})$ $\left.109.3(8), \mathrm{C}(\mathrm{I})-\mathrm{P}-\mathrm{C}\left(\mathrm{l}^{\prime}\right) 109.5(6)^{\circ}\right]$. The $\mathrm{P}-\mathrm{C}(\mathrm{Me})$ distance

| * The scattering factor is of the form $f=f_{0} \exp \left[-\left(b_{11} h^{2}+b_{22} k^{2}+b_{33} l^{2}+b_{12} h k+b_{13} h l+b_{23} k l\right)\right]$. |  |  |  |  |  |  |

where $w=4\left|F_{0}\right|^{2} / \sigma^{2}\left(F_{0}{ }^{2}\right)$. For atoms on special positions only one third of the calculated parameter shifts were applied. After two cycles with all atoms isotropic, $R 0.096$ and $R^{\prime} 0.113$ $\left\{R^{\prime}=\left[\Sigma w\left(\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|\right)^{2} / \Sigma w F_{0}{ }^{2}\right]^{\mathbf{d}}\right\}$. All atoms were then assigned anisotropic thermal parameters, with those for atoms on the special positions $x, x, x$ being constrained such that $\beta_{11}=\beta_{22}=\beta_{33}$ and $\beta_{12}=\beta_{13}=\beta_{23}{ }^{.25}$ As before, the appropriate fractional shifts were applied to these variables and the affected parameters were reset after each cycle. After 4 cycles, refinement converged with $R 0.038$ and $R^{\prime}$ 0.048 . During the latter stages of refinement the weighting scheme was checked by analysis of $\left\langle\Sigma w \Delta^{2}\right\rangle$ throughout the data and found to be satisfactory. Final atomic coordinates and thermal parameters are given in Tables 2 and 3 respectively, together with their estimated standard deviations. Tables of observed and calculated structure factors are deposited with Supplementary Publication No. SUP 21787 ( 6 pp ., 1 microfiche).*

## discussion

Description of the Structure.-The crystal structure consists of discrete $\left[\mathrm{Ph}_{3} \mathrm{MeP}\right]^{+}$and $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ions.

[^1]$[1.81(2) \AA]$ is longer than $\mathrm{P}-\mathrm{C}(1)[1.79(1.5) \AA]$ as would be expected, although the difference here is not significant. The phenyl $\mathrm{C}-\mathrm{C}$ bond distances range from $1.33(3)$

Figure 3 A view of the superimposed $\mathrm{Cu}_{4}$ tetrahedra. Hatched circles represent one set of copper atoms, cross-hatched circles represent the other

Figure 4 The geometry of the $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ion. Standard deviations in bonds and angles are $0.005 \AA$ and $0.2^{\circ}$ respectively attached octahedral array of iodine atoms. Each individual $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ cluster consists, then, of a nonbonded tetrahedron of copper atoms with each pair of
copper atoms being bridged by an iodine atom lying out from the tetrahedron edge. The geometry of one such ion is illustrated in Figure 4. Although each $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ion has potential $T_{d}$ symmetry, the particular arrangement of the individual atoms causes one three-fold axis of the $T_{a}$ point-group to be unique and therefore the overall anionic symmetry reduces to $C_{3 v}$. Thus, $\mathrm{Cu}(1)$ which lies on the unique three-fold axis is crystallographically different from $\mathrm{Cu}(21), \mathrm{Cu}(22)$, and $\mathrm{Cu}(23)$.

The non-equivalence of the copper atoms confirms the explanation given previously ${ }^{18}$ for the observed splitting patterns for the copper and iodine n.q.r. signals. The ${ }^{63} \mathrm{Cu}$ n.q.r. frequencies at 26.8 and $26.15 \mathrm{MHz}(77 \mathrm{~K})$ can be assigned on the basis of their relative intensities to $\mathrm{Cu}(1)$ and the set $\mathrm{Cu}(21), \mathrm{Cu}(22), \mathrm{Cu}(23)$ respectively. The presence of two closely spaced ${ }^{127}$ I n.q.r. signals of approximately equal intensity can likewise be explained by the presence of two inequivalent sets of iodine atoms, $\mathrm{I}(1)-(3)$ and $\mathrm{I}(4)-(6)$.

The co-ordination geometry of all four copper atoms is approximately trigonal planar. $\mathrm{Cu}(1)$ is symmetrically bonded to $\mathrm{I}(\mathrm{I}), \mathrm{I}(2)$, and $\mathrm{I}(3)$ (Figure 4) with $\mathrm{I}-\mathrm{Cu}(1)-\mathrm{I}$ angles of $119.2(2)^{\circ}$ and is displaced $0.240 \AA$ from the plane of the three iodine atoms towards the centre of the $\mathrm{Cu}_{4}$ tetrahedron. The $\mathrm{I}-\mathrm{Cu}-\mathrm{I}$ angles about the remaining three copper atoms are 120.1, 121.6, and $117.9(2)^{\circ}$. These copper atoms are displaced towards the centre of the ion by only $0.100 \AA$ from the planes of their respective iodine atoms. The $\mathrm{Cu}-\mathrm{I}$ bond distances are 2.539, 2.541, 2.578, and 2.638(5) $\AA$ (Figure 4). These values compare with $\mathrm{Cu}-\mathrm{I}$ distances in other recently reported three-co-ordinate complexes. The most directly comparable are for those atoms in the $(\mathrm{CuI})_{4}$ ' step' structures where the co-ordination numbers of copper and iodine are 3 and 2 respectively. In $\left[\left\{\left(\mathrm{PPh}_{3}\right) \mathrm{CuI}\right\}_{4}\right]$ the $\mathrm{Cu}-\mathrm{I}$ distance is $2.527(2) \AA ;{ }^{14}$ in $\left[(\mathrm{CuI})_{4}(\mathrm{dpm})_{2}\right][\mathrm{dpm}=$ bis(diphenylphosphino)methane] it is $2.510(4) ~ \AA \AA .{ }^{15}$ When the copper and iodine co-ordination numbers are both 3 the distances increase to $2.592(2)$ and 2.718(4) $\AA .^{14,15}$ The $\mathrm{Cu}-\mathrm{I}-\mathrm{Cu}$ angles in $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}[63.9(2)$ and $\left.65.2(2)^{\circ}\right]$ are close to those described for two-co-ordinate iodine in the $(\mathrm{CuI})_{4}$ step structures. In $\left[\left\{\left(\mathrm{PPh}_{3}\right) \mathrm{CuI}\right\}_{4}\right]$ and $\left[(\mathrm{CuI})_{4}(\mathrm{dpm})_{2}\right]$ the appropriate $\mathrm{Cu}-\mathrm{I}-\mathrm{Cu}$ angles are $66.80(7)$ and $62.9(4)^{\circ} .{ }^{14,15}$ A similar value $\left[63.9(2)^{\circ}\right]$ has been found in the four-co-ordinate copper complex $\left[\{\mathrm{CuI}(\text { nas })\}_{2}\right][$ nas $=$ (o-dimethylaminophenyl)dimethylarsine]. ${ }^{31}$

Non-bonded Approach Distances.--The tetrahedron formed by the four copper atoms has relatively short $\mathrm{Cu} \cdots \mathrm{Cu}$ distances: $\mathrm{Cu}(\mathrm{l}) \cdots \mathrm{Cu}(21) \quad 2.742(7)$ and $\mathrm{Cu}(21) \cdots \mathrm{Cu}(22) 2.757(7) \AA$. These compare with the corresponding distances in $\left[\left(\mathrm{PEt}_{3} \mathrm{CuI}\right)_{4}\right][2.927(2) \AA]^{10}$ and $\left[\left(\mathrm{AsEt}_{3} \mathrm{CuI}\right)_{4}\right][2.783(2) \AA] .{ }^{12}$ In the related bro-

[^2]mide and chloride complexes the $\mathrm{Cu} \cdots \mathrm{Cu}$ distances are all longer ( $3.0-3.4 \AA$ ). ${ }^{11}$

The octahedron of iodine atoms is slightly distorted by a small elongation along the $\overline{3}$ axis, giving I $\cdot$ I I separations of 4.38 and $4.52 \AA$.

The most likely explanation for the observed distortions of the copper and iodine polyhedra are the interionic approaches. The two shortest I $\cdot \mathrm{C}(\mathrm{Ph})$ distances are only $3.85(2)$ for $\mathrm{I} \cdots \mathrm{C}(5)$ and $3.92(2) \AA$ for $\mathrm{I} \cdots \mathrm{C}(6)$. Perhaps of more significance is the close approach of $3.46(2) \AA$ between $\mathrm{Cu}(1)$ and $\mathrm{C}(\mathrm{Me})$. The van der Waals radius of copper is not known accurately but it is possible to estimate its likely value as being of the order of $2.2 \AA$ by comparison with published values for other elements. ${ }^{32}$ The van der Waals radius for a methyl group has been listed as $2.0 \AA^{33}$ giving a total $\mathrm{Cu} \cdots \mathrm{C}(\mathrm{Me})$ van der Waals contact distance of $4.2 \AA$. Thus the observed separation of $3.46 \AA$ is very short indeed.

The relative orientation of the anions and cations in the crystal explains the unusually large low-frequency shift of the methyl rocking band in the i.r. spectrum. ${ }^{18}$ The short $\mathrm{Cu}(1) \cdots \mathrm{C}(\mathrm{Me})$ distance $(3.46 \AA)$, and the fact that $\mathrm{Cu}(1)$ experiences a greater displacement $(0.240 \AA)$ from the plane of its co-ordinated iodine atoms than $\mathrm{Cu}(21), \mathrm{Cu}(22)$, and $\mathrm{Cu}(23)(0.100 \AA)$ suggests the presence of a repulsive interaction between the methyl group and $\mathrm{Cu}(1)$. If this repulsion is greatest for the equilibrium configuration, and is less for displacements of the methyl group along the rocking co-ordinate, then this interaction would result in a 'flattening' of the potential well for the rocking mode, with a concomitant decrease in the frequency of this vibration. The unusual increase in intensity of the methyl symmetric bending mode in the i.r. ${ }^{18}$ might also be the result of a repulsive interaction of the type described, although it is not so easy to postulate a specific mechanism in this case.

The co-ordination geometry in the present compound can be compared with that in $\left[\left(\mathrm{Et}_{2} \mathrm{NCS}_{2}\right) \mathrm{Cu}\right]_{4},{ }^{34}\left[\left(\mathrm{Pr}_{2}-\right.\right.$ $\mathrm{NCOS}) \mathrm{Cu}]_{6}{ }^{35} \quad\left[\left(\mathrm{Pr}_{2} \mathrm{NCS}_{2}\right) \mathrm{Ag}\right]_{6}{ }^{36}$ and $\left[\mathrm{PhMe}_{3} \mathrm{P}_{4}\left[\mathrm{Cu}_{8}{ }^{-}\right.\right.$ $\left.\left\{\mathrm{S}_{2} \mathrm{C}_{2}(\mathrm{CN})_{2}\right\}_{6}\right] \cdot{ }^{37}$ In each of these compounds the metal atoms exhibit trigonal, almost planar, co-ordination to ligands which bridge pairs of metal atoms to form a polyhedral cluster. As in the present case, the deviation from planar co-ordination involves a slight displacement of the metal atom towards the centre of the polyhedron. Trigonal co-ordination of copper(r), while still quite rare in comparison with tetrahedral co-ordination, is also known in a number of mononuclear complexes (see ref. 38, and refs. therein). The ${ }^{63} \mathrm{Cu}$ n.q.r. frequencies for $\left[\mathrm{Ph}_{3} \mathrm{MeP}\right]_{2}\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right] \quad(26.15$ and 26.8 MHz at 77 K$),{ }^{18}$ $\left[\left(\mathrm{Et}_{2} \mathrm{NCS}_{2}\right) \mathrm{Cu}\right]_{4}(26.96 \mathrm{MHz}$ at 293 K$),{ }^{39}$ and $\left[\left(\mathrm{Me}_{3} \mathrm{PS}\right)_{3}{ }^{-}\right.$ $\mathrm{Cu}]\left[\mathrm{ClO}_{4}\right]$ ( 26.35 MHz at $77 \mathrm{~K}, 25.07$ at $c a .290 \mathrm{~K}$ ), ${ }^{38}$

[^3]all of which involve trigonal co-ordination of copper(1), are similar in magnitude, and comments which have been made concerning the origin of the electric-field gradient at the copper nucleus and the nature of the bonding in the latter compound ${ }^{38}$ could also apply to the other two.

The question of the possible existence of metal-metal bonding in polynuclear copper complexes, and the relationship of the metal-metal distance to bond order has been the subject of some discussion recently. $31,37,40-48$ $\mathrm{Cu} \cdots \mathrm{Cu}$ bond orders of $1, \frac{3}{4}$, and $\frac{2}{3}$ have been deduced for the compounds $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{CuH}\right]_{6}[d(\mathrm{Cu} \cdots \mathrm{Cu}) 2.494-$ $2.674 \AA],{ }^{47}\left[\mathrm{Ph}_{3} \mathrm{PIr}\right]_{2}\left[\mathrm{Cu}_{4}(\mathrm{C}: \mathrm{CPh})_{8}\right](2.665-2.823 \AA),{ }^{48}$ and $\quad\left[\mathrm{PhMe}_{3} \mathrm{P}\right]_{4}\left[\mathrm{Cu}_{8}\left\{\mathrm{~S}_{2} \mathrm{C}_{2}(\mathrm{CN})_{2}\right\}_{6}\right] \quad(2.783-2.871 ~ \AA) .{ }^{37}$ These bond orders were deduced by use of the 'inert gas ' or eighteen-electron rule, which accounts very well for the structures of a large number of transition-metal carbonyl clusters. The second of the aforementioned three compounds involves copper with a formal oxidation state of zero, ${ }^{48}$ with no bridging ligands, so the postulated existence of copper-copper bonding in this compound seems reasonable. In the other two compounds, however, the copper atoms have formal oxidation states of unity, and are directly bonded to bridging ligands. As there are several mononuclear copper(I) complexes which do not obey the eighteen-electron rule (e.g. the trigonal mononuclear complexes referred to), the use of this rule to determine the presence or otherwise of metal-metal bonding in these polynuclear complexes must be open to question. For example, it was not considered necessary to invoke metal-metal bonding to account for the structure of tetrameric (4-methyl-2-cupriobenzyl)dimethylamine, in spite of the presence of the very short copper-copper distances of 2.377 and $2.389 \AA$, the shortest yet reported for a polynuclear copper complex. ${ }^{41}$

It seems likely that copper-copper distances in cluster compounds involving bridging ligands are determined at least partly by the bonding requirements of the bridging ligand, so that this distance in itself is not likely to be a very reliable measure of the extent of copper-copper bonding. Clearly the measurement of some other property more directly related to metal-metal bond strengths would be required. It might therefore be useful to note that the main features of the vibrational spectrum of the $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$ ion (with the geometry determined here) can be accounted for by means of a very simple valence force-field which does not include a

[^4]force constant corresponding to a direct $\mathrm{Cu} \cdots \mathrm{Cu}$ interaction (Figure 5 of ref. $18, \beta \approx 65^{\circ}$ ).

As the present work yields the first definitive structure for an anion of the formal type $\left[\mathrm{M}_{2} \mathrm{X}_{3}\right]_{n}{ }^{n-}$ ( $\mathrm{M}=$ group Ib metal, $\mathrm{X}=$ halogen), it is interesting to compare this with the structures of other ions of this stoicheiometry which have been previously suggested.

The existence of an anion $\left[\mathrm{Ag}_{4} \mathrm{I}_{6}\right]^{2-}$, with a structure similar to that found here for $\left[\mathrm{Cu}_{4} \mathrm{I}_{6}\right]^{2-}$, has been postulated on the basis of molecular weight and $X$-ray diffraction studies of KI/AgI solutions in acetone. ${ }^{49}$ The structure which fits the $X$-ray diffraction data best has $\mathrm{Ag}-\mathrm{I} 2.85 \AA, \mathrm{I}-\mathrm{Ag}-\mathrm{I} 111^{\circ}$, and $\mathrm{Ag}-\mathrm{I}-\mathrm{Ag} 106^{\circ}$. These results imply tetrahedral co-ordination of the silver, with the fourth co-ordination position possibly being occupied by a solvent molecule.

A number of salts of composition $\mathrm{M}\left[\mathrm{Cu}_{2} \mathrm{Cl}_{3}\right]\{\mathrm{M}=$ $\left[\mathrm{Et}_{3} \mathrm{PH}\right]^{+},\left[\mathrm{Et}_{3} \mathrm{NH}\right]^{+},\left[\mathrm{Bu}_{3} \mathrm{NH}\right]^{+}$, and $\left.[\mathrm{EtPipH}]^{+}\right\}$which are liquids at room temperature have been reported recently. ${ }^{50}$ The i.r. and Raman bands assigned to the anions in these compounds are very broad, and it is likely that a number of anionic complexes are present in equilibrium. A hypothetical $\left[\mathrm{Cu}_{2} \mathrm{Cl}_{3}\right]^{-}$ion with a $C_{2 v}$ structure involving two terminal and one bridging chloride was considered in a discussion of the vibrational spectra, but the spectral data are not good enough to allow distinction between this and alternative structures.

The possible existence of an anion of the type $\left[\mathrm{Cu}_{8}^{-}\right.$ $\left.\mathrm{X}_{12}\right]^{4-}(\mathrm{X}=\mathrm{Br}$ or I$)$, with a structure similar to that found for the anion in $\left[\mathrm{PhMe}_{3} \mathrm{P}_{4}\left[\mathrm{Cu}_{8}\left\{\mathrm{~S}_{2} \mathrm{C}_{2}(\mathrm{CN})_{2}\right\}_{6}\right]\right.$, has been postulated on the basis of the similarity in coordination properties of the sulphur atoms in the $\left[\mathrm{S}_{2} \mathrm{C}_{2}\right.$ $(\mathrm{CN})_{2}{ }^{2-}$ ligand and the heavy halide ions. ${ }^{37}$ Similar arguments can be applied to the copper 1,1-diethoxy-carbonyl-2,2-ethylenedithiolato- and dithiosquaratocomplexes. ${ }^{44}$ Such an ion would consist of a cube of eight copper atoms, with halide ions bridging pairs of copper atoms along the 12 edges of the cube. It is now clear, however, that essentially the same co-ordination geometry about the copper atoms can be achieved in an ion of the type $\left[\mathrm{Cu}_{4} \mathrm{X}_{6}{ }^{2-}\right.$, the structure being based on tetrahedron rather than on a cube. It is not yet clear what factors determine the number of metal atoms incorporated in bridged clusters of this type. In this connection, a recently reported compound formulated as $\left[\mathrm{Ph}_{4} \mathrm{P}\right]_{4}\left[\mathrm{Cu}_{8}(\mathrm{SPh})_{12}\right]^{51}$ might, in view of the present results, have the formula $\left[\mathrm{Ph}_{4} \mathrm{P}\right]_{2}\left[\mathrm{Cu}_{4}(\mathrm{SPh})_{6}\right]$.
