# Aryltriazenido-complexes. Crystal and Molecular Structure of trans-Carbonyl(1,3-di-p-tolyltriazenido)bis(triphenylphosphine)iridium(1) 

By Attilio Immirzi and William Porzio, Istituto di Chimica delle Macromolecole del C.N.R., Via Corti 12, 20133 Milano, Italy<br>Gabriella Bombieri,* Laboratorio di Chimica e Tecnologia dei Radioelementi del C.N.R., Corso Stati Uniti, Padova, Italy<br>Luigi Toniolo, Istituto di Chimica Generale dell'Università, Padova, Italy

The structure of the title compound has been determined by counter data. In this square-planar iridium complex the triazenido-ligand is unidentate and trans to the carbonyl group. The $\operatorname{Ir}-\mathrm{N}(1)$ distance is 2.16 (1) and the $\operatorname{Ir}-\mathrm{C}(26)$ (carbonyl) $1.79(1) \AA$. The complex crystallizes in the monoclinic system, space group $C 2 / c$, with unitcell dimensions $a=22.121(3), b=19.190(3), c=10.111(2) A$, and $\beta=92.77(5)^{\circ}$. The structure is refined to a conventional $R$ index of 0.032 .

THE 1,3-diaryltriazenido-ligand $p-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~N}-\mathrm{N}=\mathrm{NC}_{6} \mathrm{H}_{4}-$ $\mathrm{CH}_{3}-p$ (dtt) is unidentate in palladium(II) and platinum(II) square-planar complexes. ${ }^{1-4}$ Variable-temperature ${ }^{1} \mathrm{H}$ n.m.r. experiments on these complexes have shown that the two signals for the methyl protons collapse reversibly between -40 and $-60^{\circ} \mathrm{C}$ giving rise to a unique signal at higher temperature indicating a fluxional process. For the title complex $\left[\operatorname{Ir}(\mathrm{CO})(\mathrm{dtt})\left(\mathrm{PPh}_{3}\right)_{2}\right]$ the nitrogen atoms remain equivalent even down to $-90^{\circ} \mathrm{C}$ (in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ ) suggesting either the occurrence of a dynamic process or the presence of a chelating ligand. The i.r. spectrum shows bands at $1361,1302,1278,1211$, and $1157 \mathrm{~cm}^{-1}$ which have been proposed as diagnostic for the dtt group acting as a unidentate ligand. ${ }^{5,6}$

In order to understand better the bonding mode of the dtt ligand in the title complex its crystal structure has been studied by $X$-ray diffraction methods.

## RESULTS AND DISCUSSION

Crystal Data.-Orange prismatic crystals ( $0.1 \times 0.2$ $\times 0.1 \mathrm{~mm})$, Monoclinic, space group $C 2 / c, a=22.121(3)$, $b=19.190(3), \quad c=10.111(2) \quad \AA, \quad \beta=92.77(5)^{\circ}, \quad U=$ $4287 \AA^{3}, D_{\mathrm{c}}=1.48 \mathrm{~g} \mathrm{~cm}^{-3}, Z=4, \mu=35.2 \mathrm{~cm}^{-1}$, Mo- $K_{\alpha}$ radiation, $\lambda=0.71069 \AA$.

Intensity Data, Structure Determination, and Refine-ment.-A total of 3370 independent reflections were collected by means of a Philips PW 1100 four-circle diffractometer $\left(3<0<24^{\circ}, \quad d_{\text {min. }}=0.87 \AA\right)$ using a graphite monochromator; of these, 2835 having $I>$ $3 \sigma(I)$ ( $\sigma$ based on counting statistics) were used in the structure determination and refinement. Corrections for Lorentz and polarization effects were applied, while absorption correction was disregarded, due to the crystal size.

Systematic absences and Patterson-function examination confined the choice of space group to $C c$ without any molecular symmetry or $C 2 / c$ with a $C_{2}$ symmetry axis.

From the Patterson function the positions of Ir and P atoms were found to conform to $C 2 / c$ symmetry and the electron-density map phased with the above contributions confirmed the two-fold molecular symmetry, likewise for the $\mathrm{PPh}_{3}$ groups. In the region of the dtt
ligands, however, the electron-density map showed elongated peaks indicating either: (i) that the true symmetry is lower, without a two-fold axis; or (ii) that the two-fold axis does exist in the crystal but is derived from the occurrence of two statistically equivalent orientations for dtt . In the first case the space group should be $C c$ in the second $C 2 / c$. However, in both hypotheses the dtt group behaves as a unidentate ligand bonding through a single nitrogen atom.

The two models were refined by least squares with block-diagonal approximation for the whole structure, except for the dtt ligand which was refined by fullmatrix least squares. Anisotropic thermal-vibration parameters were considered for iridium and the triphenylphosphine ligand and isotropic parameters for all other non-hydrogen atoms. In both cases the two $\mathrm{PPh}_{3}$ groups remained symmetrically related. In the last cycles of refinement the hydrogen-atom contribution was considered by calculating the atomic positions of phosphine hydrogens, assuming the usual geometry for phenyl groups.

Comparison of the observed structure factors with the calculated ones for either $C c$ or $C 2 / c$ models shows only very slight differences between them since most atoms conform to the higher symmetry in both cases. In fact the conventional $R$ indices are quite similar: 0.033 for $C c$ and 0.032 for $C 2 / c$. This does not allow a definite determination of the crystal symmetry on structurefactor grounds only. Furthermore, comparison of the resulting geometry for the dtt ligand does not help in discriminating between the two models since bond lengths and angles are equal within error limits. The C2/c space group, however, appears more likely on crystalpacking grounds: the absence of $\mathrm{dtt} \cdot \cdots \mathrm{dtt}$ short contacts and the $C_{2}$ symmetry of the 'cavity' available for the ligand make the two ligand orientations energetically equivalent and hence favoured by entropy considerations.

Observed and calculated structure factors and thermal parameters are available as Supplementary Publication No. SUP 22734 (25 pp.). $\dagger$ The atomic scattering factors used were those given in ref. 7 while the anomal-

[^0]onus dispersion corrections for iridium and phosphorus atoms were taken from ref. 8. The computations were carried out using programs by Immirzi. ${ }^{9}$

Description of the Structure.-The projection of the structure along the $z$ axis, obtained with the program ORTEP (see the Figure), shows the whole molecule and the crystal packing.
bonded to the dit ligand $\{2.09(2) \AA$ in trans $-[\mathrm{PtH}(\mathrm{dtt})$ $\left.\left(\mathrm{PPh}_{3}\right)_{2}\right]^{3}$ and $2.11(2) \AA$ in cis- $\left.\left[\mathrm{PtCl}(\mathrm{dtt})\left(\mathrm{PPh}_{3}\right)_{2}\right]^{4}\right\}$ and with the values of $2.089(6)$ and $2.088(5) \AA$ reported for cis- $\left[\mathrm{Pt}\left(\mathrm{PhN}_{3} \mathrm{Ph}\right)_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right] \cdot \mathrm{C}_{6} \mathrm{H}_{6} \cdot{ }^{12}$

The ot ligand has a trans conformation with respect to both $\mathrm{N}(2)-\mathrm{N}(3)$ and $\mathrm{N}(1)-\mathrm{N}(2)$ bonds, as a consequence the $\mathrm{C}(1)-\mathrm{N}(1)-\mathrm{N}(2)-\mathrm{N}(3)-\mathrm{C}(1)$ group is fairly planar.

-

View down the $c$ axis of the molecule (only one of the two alternative orientations of dit is indicated for clarity)

Principal interatomic distances and angles are given in Table 1. The co-ordination around the Ir is nearly square planar, with the two $\mathrm{PPh}_{3}$ groups trans to each other.

The carbonyl group shows distances comparable to carbonyls in other iridium compounds. The present iridium-carbon distance of $1.79(1) \AA$ is comparable with the values of $1.800(8) \AA$ reported for $\left[\operatorname{Ir}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\right.$ (CO) $\left.\left(\mathrm{PPh}_{3}\right)\right]^{10}$ and falls in the range excepted for this type of bond. The iridium-phosphorus distance $2.316(1)$ is comparable with the values of $2.316(5)$ and $2.329(5) \AA$ found in $\left[\operatorname{Ir}\left(\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{Me}\right)\left(\mathrm{PPhMe}_{2}\right)_{2}\right]^{11}$ and related compounds. The iridium-nitrogen bond length $2.16(1) \AA$ is in agreement with the metal-nitrogen bonds in square-planar compounds containing platinum

The mean plane of dtt forms an angle of $\mathbf{8 2 ^ { \circ }}$ with the mean co-ordination plane.

The asymmetry of the dit ligand and the $C 2 / c$ crystal symmetry imply that there are two statistically equivalent orientations for the gt ligand (in both cases dit is unidentate), that may correspond either with a space disorder or a time disorder, ie. in the latter case, a fluxional process in the crystal.

In fact diffraction cannot distinguish between static disorder and dynamic disorder. Nevertheless, the symmetric orientation of the two phosphines and the arrangement of att in the crystal should make the fluxional processes available not only in solution but also in the crystal. In fact, the intermolecular contacts which control the size of the unit cell are all among the
phenyl group and there are no short $\mathrm{dtt} \cdot \mathrm{dtt}$ or dtt . . . phenyl contacts (none are less than $3.9 \AA$ ). This possibility is also suggested by the short $\operatorname{Ir} \cdots \mathrm{N}(3)$ contact $[2.58(1) \AA]$, compared with the analogous contacts in trans- $\left[\mathrm{PtH}(\mathrm{dtt})\left(\mathrm{PPh}_{3}\right)_{2}\right][2.91(2) \AA]$ and in cis$\left[\mathrm{PtCl}(\mathrm{dtt})\left(\mathrm{PPh}_{3}\right)_{2}\right][3.01(2) \AA]$ which would make the dynamic process easier. These observations and the magnetic equivalence of the methyl protons observed in

solution $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$ even down to $-90^{\circ} \mathrm{C}$ strongly support the existence of a fluxional process in the solid state at room temperature.

All C-C distances (see Table 2) differ from the expected values to within $0.06 \AA$ for the phosphine (mean $\mathrm{C}-\mathrm{C}=$
$1.396 \AA$ ) and $0.08 \AA$ for the triazenido-rings (mean $\mathrm{C}-\mathrm{C}$ $=1.412 \AA)$, except for the $\mathrm{C}(4)-\mathrm{C}(5)$ and $\mathrm{C}\left(4^{\prime}\right)-\mathrm{C}\left(5^{\prime}\right)$ distances. We do not think that such anomalous values for these distances have any physical significance and

they are attributed to the very high correlation between the two methyl groups; such effects are enhanced by the exceedingly high thermal vibration for the methyl groups.
[9/550 Received, 6th April, 1979]
