# Crystal and Molecular Structure of an Unsubstituted Bis(phenoxo)derivative of Copper(II), the $\left[\left\{\mathrm{Cu}(\mathrm{OPh})_{2}(\mathrm{en})\right\}_{2}\right] \cdot 2 \mathrm{PhOH} \dagger$ Dimer, with a ' Normal ' Magnetic Moment at Room Temperature 

By Fausto Calderazzo,* Fabio Marchetti, and Giancarlo Dell'Amico, Istituto Chimica Generale, University of Pisa, Via Risorgimento 35, 56100 Pisa, Italy<br>Giancarlo Pelizzi, Istituto Chimica Generale, University of Parma and Centro Strutturistica Diffrattometrica, C.N.R., Via Massimo D'Azeglio 85, 43100 Parma, Italy<br>Arturo Colligiani, Laboratorio Chimica Quantistica ed Energetica Molecolare, C.N.R., Via Risorgimento 35, 56100 Pisa, Italy

#### Abstract

The title compound has been shown by $X$-ray diffraction methods to be a centrosymmetric phenoxo-bridged dimer with terminal phenoxo- and ethylenediamine groups and hydrogen-bonded phenol molecules. The crystals are monoclinic, space group $P 2_{1} / n$, and the unit cell has dimensions $a=19.000(13), b=10.930(9), c=8.968(5) \AA$, $\beta=89.90(2)^{\circ}, U=1862.4 \AA^{3}$, and $Z=4$. The structure was refined by three-dimensional Patterson and Fourier techniques up to a conventional $R$ value of 0.0437 . The copper atoms are five-co-ordinate and the coordination geometry is that of a distorted square pyramid. The $\mathrm{Cu} \cdots \mathrm{Cu}$ distance is $3.215 \AA$. The compound has a nearly normal magnetic moment at room temperature and the results of the present investigation are discussed in connection with the known magnetic and structural data for dimeric oxygen-bridged copper(II) complexes.

Some of us have recently reported ${ }^{1}$ the preparation of the first stable unsubstituted bis(phenoxo)-derivative of copper(II) with $2,2^{\prime}$-bipyridyl (bipy) and ethylenediamine (en) of formula $\left[\mathrm{Cu}(\mathrm{OPh})_{2}(\right.$ bipy $\left.)\right]$ (1), and $[\mathrm{Cu}-$ $\left.(\mathrm{OPh})_{2}(\mathrm{en})\right] \cdot \mathrm{PhOH}$, (2) respectively. Monomeric structures were assigned to these compounds on the basis of spectroscopic results and the normal paramagnetic behaviour observed at room temperature.

We now report that the $X$-ray investigation of one of these compounds, (2), has revealed that it is in fact dimeric, $\left[\mathrm{Cu}_{2}(\mathrm{OPh})_{4}(\mathrm{en})_{2}\right] \cdot 2 \mathrm{PhOH}$, with bridging phen-oxo-groups and thus it belongs to the class of the oxygenbridged copper(II) dimers. ${ }^{2}$ Its structural details appear to be of general interest for co-ordination chemists, especially in connection with the ' normal' magnetic behaviour observed at room temperature.

## EXPERIMENTAL

The e.s.r. spectra were measured with a Varian E-112 Century Series spectrometer, by operating in the $X$-band and by magnetic modulation at 100 kHz .

Preparation of $\left[\mathrm{Cu}_{2}(\mathrm{OPh})_{4}(\mathrm{en})_{2}\right] \cdot 2 \mathrm{PhOH}$.-The title compound was prepared by a slightly modified version of the procedure already reported. ${ }^{1}$ All solvents and reagents were carefully dried prior to use. The preparation was carried out under an atmosphere of nitrogen dried over $\mathrm{P}_{4} \mathrm{O}_{10}$. A solution of phenol $(4.645 \mathrm{~g}, 49.3 \mathrm{mmol})$ in tetrahydrofuran (thf) $\left(350 \mathrm{~cm}^{3}\right)$ was treated with sodium sand ( $0.73 \mathrm{~g}, 31.75 \mathrm{mmol}$ ) at room temperature. The resulting solution of sodium phenoxide and phenol was added to the suspension of $\mathrm{CuCl}_{2}(2.166 \mathrm{~g}, 16.11 \mathrm{mmol})$ in diethyl ether $\left(25 \mathrm{~cm}^{3}\right)$ containing ethylenediamine ( $0.953 \mathrm{~g}, 15.86 \mathrm{mmol}$ ). After ca. 40 h stirring, the resulting deep green solution was filtered, in order to eliminate sodium chloride. Evaporation of the solution to about one eighth its original volume under reduced pressure gave rise to the incipient precipitation of the microcrystalline complex. The precipitate was dissolved by heating briefly to $c a .50^{\circ} \mathrm{C}$ and the resulting solution was then kept in the refrigerator overnight.

[^0]The crystalline complex was filtered off and dried in vacuo $(2.17 \mathrm{~g}, 33.3 \%$ yield). Attempts were not made to optimize the yields. The compound analyzed correctly for the formulation given. The solution of the compound in thf is extremely sensitive to moisture.

A polycrystalline sample of the compound gave the e.s.r. spectrum of Figure 1, with a main line at $g=2.09$ and a very weak line at $g=4.25$. From the integrated area of these signals and from the weight of the sample, by using copper(II) sulphate as standard, it was calculated that $5.8 \times$ $10^{23}$ unpaired spins were present per mole of copper in the substance. Several measurements of the magnetic susceptibility at room temperature (Faraday method) gave values of the magnetic moment ranging from 1.7 to 1.8 B.M. + (diamagnetic correction $=-2.94 \times 10^{-9} \mathrm{~m}^{3} \mathrm{~mol}^{-1}$ ). A $X$-ray powder diagram (see Table 1) of the polycrystalline substance prepared as described above could be indexed with the cell parameters found for the single crystal (see below). The polycrystalline substance after exposure to air (ca. 2 h ) had identical $X$-ray powder pattern and identical e.s.r. signals.

Crystal Data and Data Collection.-For the $X$-ray investigation, single crystals were grown from thf solution. The single crystal used for the structural determination was sealed in a Lindemann capillary under nitrogen saturated with thf. The unit-cell dimensions, originally obtained from rotation and Weissenberg photographs, were refined by a least-squares procedure on the setting angles of 17 strong reflections accurately measured on a single-crystal Siemens AED diffractometer. The crystals were found to belong to the monoclinic system. The observed extinctions of $h 0 l, h+l=2 n+l$ and $0 k 0, k=2 n+l$ uniquely determined the space group to be $P 2_{1} / n$, a non-standard setting of $P 2_{1} / c\left(C_{2 h}^{5}\right.$ no. 14), that was retained because of its more nearly orthogonal $\beta$ angle.

Crystal data are as follows: $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{CuN}_{2} \mathrm{O}_{3}, \quad M=$ 403.9, Monoclinic, $a=19.000(13) . \quad b=10.930(9), \quad c=$ $8.968(5) \AA, \beta=89.90(9)^{\circ}, U=1862.4 \AA^{3}, Z=4, D_{c}=$ $1.440 \mathrm{~g} \mathrm{~cm}^{-3}, F(000)=844$, Mo- $K_{\alpha}$ radiation, $\lambda=0.71069$ $\AA ; \mu\left(\mathrm{Mo}-K_{\alpha}\right)=11.3 \mathrm{~cm}^{-1}$.

The $X$-ray intensity data were recorded using a crystal of
$\ddagger$ Throughout this paper: 1 B.M. $=9.274 \times 10^{-24} \mathrm{~A} \mathrm{~m}^{2}$.
approximate dimensions $0.18 \times 0.31 \times 0.52 \mathrm{~mm}$ sealed in a Lindemann-glass capillary and mounted with its $c$ axis coincident with the $\phi$ axis of the Siemens diffractometer. Niobium-filtered Mo- $K_{\alpha}$ radiation and the moving-counter-moving-crystal procedure with a take-off angle of $4^{\circ}$ were used to collect data for an octant of the reciprocal lattice. The scan rate was $2.5^{\circ} \mathrm{min}^{-1}$. In this way the intensities of 3254 symmetry-independent reflections were measured within the $2.5-25.0^{\circ}$ range of $2 \theta$. The rejection criterion for the 1103 unobservably weak reflections, which were excluded from the crystal analysis, was $I<2 \sigma(I)$, where $\sigma(I)$ is the standard deviation of the measured intensity

* Calculated from the crystal data obtained by the singlecrystal diffractometric study.
based on counting statistics. Attenuation filters were automatically inserted between the crystal and the detector in order to stay in the linear zone of counting. Crystal and instrument stabilities were monitored throughout by remeasuring the intensity of a standard reflection every 20 measurements, without significant variation being noted. After the usual data reduction, the structure amplitudes were put on an absolute scale, first by comparison with the calculated values and then refining the scale factor for the $F_{0}$ as a variable parameter in the least-squares procedure. No absorption correction was made because of the very low

absorbance of the sample ( $r=0.14$ ). Final atomic coordinates for non-hydrogen atoms are given in Table 2, those for hydrogen atoms have been deposited as Supplementary Publication No. SUP 22752 ( 17 pp.),* together with a list of observed and calculated structure factors and thermal parameters.

Structure Determination and Refinement.-The structure was solved by three-dimensional Patterson and Fourier techniques, with successive addition of atom positions to improve the phasing for all the non-hydrogen atoms. Fullmatrix least-squares refinement, in which $\Sigma w\left(F_{0}-F_{\mathrm{c}}\right)^{2}$ was minimized, led to $R=9.64 \%$, which fell to $5.53 \%$ when anisotropic thermal parameters were introduced. At this stage all the hydrogen atoms, except those belonging to the ethylenediamine ligand, were located in their expected

Figure 3 Crystal packing of $\left[\mathrm{Cu}_{2}(\mathrm{OPh})_{4}(\mathrm{en})_{2}\right] \cdot 2 \mathrm{PhOH}$, viewed along the $b$ axis
positions from a difference synthesis and included in the refinement with isotropic thermal parameters. In the final stages of refinement each reflection was assigned a weight according to $w=1 /\left[\sigma^{2}\left(F_{0}\right)+0.005 F_{0}^{2}\right]$, chosen to minimize the variation of $w(\Delta F)^{2}$ with $\left|F_{0}\right|$ and the final residuals were $R=4.37$ and $R^{\prime}=4.74 \%$. A final difference synthesis showed no peaks higher than 0.28 e $\AA^{-3}$. At the end of refinement the shifts of the atomic parameters were negligible, all being well below the corresponding estimated standard deviations. Scattering factors for neutral atoms and correction terms for anomalous dispersion for nonhydrogen atoms ${ }^{3}$ and for hydrogen atoms ${ }^{4}$ were taken from the literature. All calculations were carried out with the programs SHELX $76^{5}$ on a Cyber 76 computer.

## RESULTS AND DISCUSSION

The $X$-ray investigation has shown that the bis-(phenoxo)-derivative of copper(II) with ethylenediamine as additional ligand is dimeric with bridging phenoxogroups, see Figure 2. The packing of the molecule in the unit cell is shown in Figure 3. The structure consists of discrete dimeric molecules with no relevant intermolecular interactions. The dimeric molecule contains a second type of phenoxo-ligands, namely the terminal

$z$. The angle between planes $\mathbf{1}$ and 2 is $89.5^{\circ}$.
copper atoms are five-co-ordinate, the set of donor atoms being of the $\mathrm{N}_{2} \mathrm{O}_{3}$ type, the two nitrogens being from the ethylenediamine, two oxygens from the bridging phen-oxo-groups, and the third oxygen from the terminal phenoxo-group. The dimeric molecule possesses a centre of inversion, thus implying that the $\mathrm{Cu}_{2} \mathrm{O}_{2}$ bridging system is strictly planar. However, the two $\mathrm{Cu}-\mathrm{O}$ (bridging) distances are markedly different (2.265 and $1.926 \AA$, see Table 3 ), a fact frequently observed in binuclear copper(II) complexes with bridging oxygens. Another phenoxo-derivative is known ${ }^{7}$ to contain phenol in its formula: however, in this case the phenol was found to be co-ordinated to the central metal atom of $\mathrm{Ti}_{2}(\mathrm{OPh})_{8} \cdot 2 \mathrm{PhOH}$ at a $\mathrm{Ti}-\mathrm{O}$ distance of $2.200 \AA$. As far as the bonding situation around the three-co-ordinated bridging oxygen is concerned stronger deviations from a $s p^{2}$ hybridisation are observed (see Tables 3 and 4), as compared with the similar cases of a molybdenum(v) ${ }^{8}$ and of two titanium(Iv) ${ }^{7,9}$ complexes. Phenoxo-bridged thallium(III) complexes have also been studied crystallographically. ${ }^{10}$

As shown by the data of Tables 4 and 5 , the coordination geometry around copper is neither trigonal

* The metal is in the basal plane.
bipyramidal nor square pyramidal. With its large anisotropy, the e.s.r. spectrum supports both these geometries and it does not allow a decision to be made in favour of either one, at least in a straightforward way. The e.s.r parameters (see Figure 1) are in close agreement with those reported for the copper(II) chelate of kojic acid ${ }^{11}$ and are consistent with the dimeric structure
samples of the compound was consistent with the cell data obtained on the single crystal. This established conclusively that the magnetic moment and the crystallographic data pertained to the same substance.

The normal magnetic moment at room temperature found for our compound is somewhat unusual for binuclear copper(II) complexes. By considering (see

determined for the single crystal. Concerning the geometry around copper, by taking into account (see Table 5) the theoretical internal bond angles for the trigonal-bipyramidal and the square-pyramidal geometries and by comparing them with the observed values, we can conclude that the geometry around copper can be described as distorted square pyramidal or very distorted trigonal bipyramidal.

The compound reported in this paper has a very normal magnetic moment at room temperature. This was confirmed by the quantitative evaluation of the e.s.r. signal. The $X$-ray powder diagram on polycrystalline

Table 6) the oxygen-bridged complexes, which are of more direct interest for the case under discussion, we can see that most of them have reduced magnetic moments at room temperature; a few cases are known of ferromagnetic behaviour, whereas 'normal' magnetic moments are seldom encountered. If copper is four-co-ordinate, the geometry of the dimer is frequently centrosymmetric and it can be represented by two basal-edged squares shown in the idealised structure (I) of Figure 4. If copper in the dimer is five-co-ordinate, and by taking into consideration the fact that the more frequently encountered geometry is that of a distorted
square pyramid, the joining of the square pyramid can ideally be obtained in one of the manners shown in Figure 4, namely, basal-edged square pyramids, (II), centrosymmetrical basal-edged square pyramids, (III), and, finally, centrosymmetric axial- and basal-edged square pyramids, (IV). Our compound belongs to this last category, as may be clearly seen from some typical parameters, namely the very different $\mathrm{Cu}^{-} \mathrm{O}$ distances within the $\mathrm{Cu}_{2} \mathrm{O}_{2}$ bridge and the almost exact orthogonality (see Table 4) of the $\mathrm{Cu}_{2} \mathrm{O}_{2}$ plane with the mean basal plane of the copper ' square pyramid '.

Several mechanisms have been proposed for the

(II)

(IV)

Figure 4 Idealised geometrical arrangements in binuclear oxygen-bridged complexes of four- and five-co-ordinate copper: (I), basal-edged squares; (II), basal-edged square pyramids; (III), centrosymmetric basal-edged pyramids; and (IV), centrosymmetric axial- and basal-edged square pyramids
magnetic interactions in binuclear copper(II) complexes. ${ }^{2,12}$ The situation concerning magnetic exchange in binuclear oxygen-bridged copper(II) complexes can be summarised as follows. The following structural parameters have been considered, among others, to be responsible for the observed phenomenon: (a) within complexes of four-co-ordinate copper, the angle at the oxygen atom of the $\mathrm{Cu}_{2} \mathrm{O}_{2}$ bridging system; (b) the angle at the copper within the non-planar $\mathrm{Cu}_{2} \mathrm{O}_{2}$ bridging systems; (c) the dihedral angle along the $\mathrm{O} \cdots \mathrm{O}$ vector of the $\mathrm{Cu}_{2} \mathrm{O}_{2}$ bridging system; and (d) the
orientation of the copper co-ordination polyhedron with respect to the $\mathrm{Cu}_{2} \mathrm{O}_{2}$ bridging system. It has also been observed by some authors ${ }^{2,13}$ that binuclear systems belonging to the class denoted as (IV) in Figure 4 usually have a low degree of magnetic interaction, if any. It is therefore not surprising that our compound, belonging to that idealised geometry has a normal magnetic moment, probably due to incorrect orientation of the metal orbitals to interact with the oxygen $p$ orbitals or, better, with themselves.

It should also be considered that, beside the geometrical factors, dynamic electronic exchange processes between the copper centres can influence the total paramagnetism of the molecule. With the aim of clarifying this point, work is now in progress to measure the e.s.r. spectra and magnetic susceptibility data at various temperatures. The results of this investigation will be reported later. ${ }^{14}$
