#### Abstract

A synthesis of the new tridentate pyridine donor ligand 2,6-bis[1-phenyl-1-(pyridin-2-yl)ethyl] pyridine, L, by reaction of 2,6-dichloropyridine with lithiated 2-(1-phenylethyl) pyridine is described. The ligand reacts with methylmercury(II) nitrate to form complexes of the meso and rac diastereoisomers of $\mathrm{L},[\mathrm{HgMe}(\mathrm{L})] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, which may be readily separated by fractional crystallization. The ligands meso-L and rac-L may be liberated from the complexes by reaction with cyanide ion in water. The crystal structure of the meso complex has been determined by singlecrystal $X$-ray diffraction at 295 K and refined by least-squares methods to $R=0.046$ for 2600 'observed' reflections [monoclinic, space group $P 2_{1} / n$, with $a=20.946(9), b=14.767(4), c=$ $9.817(3) \AA, \beta=91.12(2)^{\circ}$, and $\left.Z=4\right]$. The $[\mathrm{HgMe}(\text { meso }-\mathrm{L})]^{+}$cations have irregular co-ordination geometry for the mercury atom ' $\mathrm{HgCN}_{3}$ ' with the ligand present as a tripodal tridentate. The central nitrogen forms the strongest bond to mercury $\left[2.283(9) \AA\right.$ ] with $\mathrm{C}-\mathrm{Hg}-\mathrm{N} 166.3(5)^{\circ}$, with the other nitrogen donors 2.546 (11) and $2.595(10) \AA$ from mercury and forming $\mathrm{C}-\mathrm{Hg}-\mathrm{N}$ angles of 113.3(5) and $113.7(5)^{\circ}$, respectively. ${ }^{1} \mathrm{H}$ N.m.r. spectra for the complexes suggest that the ligand is at least bidentate in methanol.

With polydentate nitrogen-donor ligands methylmercury(iI) readily adopts co-ordination geometries higher than the characteristic linear geometry observed for unidentate ligands, ${ }^{1}$ e.g. $\left[\mathrm{HgMe}\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)\right] \mathrm{NO}_{3}\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}=\right.$ pyridine $)$ has $\mathrm{Hg}-\mathrm{N}$ 2.12(2) $\AA$ and $\mathrm{C}-\mathrm{Hg}-\mathrm{N} 179.7(6)^{\circ},{ }^{2}$ but the corresponding bis(pyridin-2-yl)methane complex has $\mathrm{Hg}-\mathrm{N}$ 2.16(1) and 2.75 (2) $\AA,{ }^{3}$ compared with an estimated value of ca. $3.23 \AA$ for the sum of mercury ${ }^{4}$ and nitrogen ${ }^{5}$ van der Waals radii. The higher co-ordination geometries are characterized by the presence of one stronger $\mathrm{Hg}-\mathrm{N}$ interaction than the other(s), with the more strongly bound nitrogen forming the largest $\mathrm{C}-\mathrm{Hg}-\mathrm{N}$ angle, e.g. with bis(pyridin-2-yl)methane the shortest $\mathrm{Hg}-\mathrm{N}$ bond forms an angle $\mathrm{C}-\mathrm{Hg}-\mathrm{N} 172(1)^{\circ}$, and the longest 106(1) ${ }^{.3}$
Although the complexes have irregular geometries for polydentates with pyridine, $N$-methylimidazole, or pyrazole donor groups, e.g. 'T-shaped' rather than trigonal for ' $\mathrm{HgCN}_{2}$ ' co-ordination in the bis(pyridin-2-yl)methane complex, two of the tridentate ligands studied have a much smaller range of $\mathrm{Hg}-\mathrm{N}$ distances and more regular geometries than complexes of other tridentate ligands. Thus, the $4,4^{\prime}, 4^{\prime \prime}$-triethyl- $2,2^{\prime}: 6^{\prime}, 2^{\prime \prime}-$ terpyridyl ( $\mathrm{Et}_{3}$-terpy) complex has distorted square-planar geometry with $\mathrm{Hg}-\mathrm{N} 2.26(2)-2.61(2) ~ \AA,{ }^{3}$ and the tris(pyridin-2-yl)methanol [(py) $\left.{ }_{3} \mathrm{COH}\right]$ complex has distorted tetrahedral geometry with $\mathrm{Hg}-\mathrm{N} 2.28(1)-2.53(1) \AA$ and $\mathrm{C}-\mathrm{Hg}-\mathrm{N} 119(1)-$ $150(1)^{\circ} .^{6}$ As both of these complexes involve pyridine donor groups, we have sought further examples of this effect via

[^0]synthesis of the new tridentate ligand 2,6-bis[1-phenyl-1-(pyridin-2-yl)ethyl]pyridine, L.

The ligand L has two chiral centres, and molecular models suggest that the meso (i.e., $R, S$ ) and $r a c(R, R$ and $S, S$ enantiomers) diastereoisomers should both be able to act as planar tridentates (as for $\mathrm{Et}_{3}$-terpy) or tripodal tridentates [as for (py) ${ }_{3} \mathrm{COH}$ towards methylmercury(II).

This paper reports the isolation of complexes of meso and rac forms of the ligand by reaction of L with $\mathrm{Hg}^{\mathrm{II}}$ Me nitrate, isolation of meso-L and rac-L from the $\mathrm{Hg}^{\mathrm{II}} \mathrm{Me}$ complexes, and an $X$-ray structural analysis of $[\mathrm{HgMe}($ meso- L$)] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. In the following paper, the synthesis of square-planar palladium(II) complexes of meso-L and rac- L are reported. ${ }^{7}$

## Results and Discussion

Synthesis and Characterization of Ligands and Complexes.-The tridentate ligand $L$ was prepared by lithiation of 2-(1phenylethyl)pyridine with phenyi-lithium followed by reaction with 2,6-dichloropyridine( $2,6 \mathrm{Cl}_{2}$-py) [equation (1)]. Methyl-

$$

L (1)
mercury(II) complexes were obtained from acetone solutions of methylmercury(iI) nitrate and the ligand, with crystals of the meso complex forming within a few hours ( $44 \%$ yield after subsequent recrystallization), and crystals of the rac complex forming from the filtrate on slow vapour diffusion of diethyl ether into the acetone solution ( $13 \%$ ).

The ligand is very insoluble in water, and thus the meso and rac diastereoisomers were readily isolated from their $\mathbf{H g}^{\text {II }} \mathrm{Me}$

\end{aligned}
$$

The complexes and $L$ have satisfactory microanalyses $(\mathrm{C}, \mathrm{H}, \mathrm{Hg}$, or N$)$ and ${ }^{1} \mathrm{H}$ n.m.r. spectra. Both complexes are hydrates, and as the meso-L complex is shown to be a dihydrate from crystallographic studies, the rac-L complex is formulated
similarly in view of the unreliability of microanalytical results in the estimation of extent of hydration. The complexes exhibit identical ${ }^{1} \mathbf{H}$ n.m.r. spectra, but slightly different i.r. spectra in the region $1100-500 \mathrm{~cm}^{-1}$.

The diastereoisomers meso- L and rac- L have identical mass spectra to that of $L$, prepared by equation (1), but slightly different melting point, i.r. spectra in the region $900-500 \mathrm{~cm}^{-1}$, and n.m.r. spectra. The meso diastereoisomer has m.p. 101101.5, rac-L 98-99.5, L 96-97, and a ca. 1:1 mixture of meso-L and rac-L 95- $96^{\circ} \mathrm{C}$. The meso and rac forms of L have slightly different $R_{\mathrm{f}}$ values, with a mixture showing two maxima in a more extended spot (meso-L $0.8-0.68$, rac-L $0.78-0.65$, mixture $0.83-0.65$, u.v. and iodine stain detection) after five developments on analytical silica gel plates with chloroform as solvent.

Structure of $[\mathrm{HgMe}($ meso-L $)] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in the Solid State.-Aspects of the geometry of $\left[\mathrm{HgMe}(\text { meso-L) }]^{+}\right.$and the nitrate ion are given in Table 1, and the cation is shown in the Figure in an orientation allowing direct comparison with $\left[\mathrm{Pd}(\text { meso }-\mathrm{L})\left(\mathrm{O}_{2} \mathrm{CMe}\right)\right]^{+}$(Figure of ref. 7). Neighbouring cations are related by inversion centres, with atoms $C(7)$ and $C(9)$, in the Figure and ref. 7 (Figure), having chirality $S$ and $R$, respectively. The nitrate ion is regular (within $2 \sigma$ in bond lengths and angles) and unco-ordinated.
meso- L is present as a tripodal tridentate ligand, with $\mathrm{N}-\mathrm{Hg}-\mathrm{N}$ angles $76.0(3)$ (rings a,b), 88.8(3) (a,c), and 75.3(3) ${ }^{\circ}$ (b,c). The central ring is more strongly bound to mercury, with $\mathrm{Hg}-\mathrm{N}(\mathrm{b} 1)[2.283(9) \AA]$ shorter than $\mathrm{Hg}-\mathrm{N}(\mathrm{a} 1)[2.546(11) \AA]$ and $\mathrm{Hg}-\mathrm{N}(\mathrm{cl})$ [2.595(10) $\AA]$. The mercury-nitrogen bond lengths differ by only $0.02-0.05 \AA$ from those of both tripodal (py) ${ }_{3} \mathrm{COH}$ and $\mathrm{Et}_{3}$-terpy, although the $\mathrm{Et}_{3}$-terpy complex has the mercury atom well removed from the mean planes of the (outer) weakly co-ordinated rings ( $-0.886,-1.032 \AA$ ) compared with -0.46 (ring a) and $-0.25 \AA$ (ring c). The central nitrogen has $\mathrm{C}-\mathrm{Hg}-\mathrm{N}(\mathrm{b} 1) 166.3(5)^{\circ}$, a value intermediate between that for the $(\mathrm{py})_{3} \mathrm{COH}\left[150(1)^{\circ}\right]$ and $\mathrm{Et}_{3}$-terpy complexes $\left[171(1)^{\circ}\right]$.

Structure of the Complexes in Methanol.-As the meso complex has two mercury-nitrogen interactions much weaker than the central pyridine interaction, it is possible that the complexes may have a different structure(s) in solution involving a lower co-ordination number(s), e.g. $\mathrm{Et}_{3}$-terpy is tridentate in the solid state but bidentate in methanol. ${ }^{3}$

For pyridine and 14 substituted pyridines, including some with substituents in the 2 - and 6 - positions, e.g. 2,6 -dimethylpyridine and the bulky - $\mathrm{CHPh}_{2}$ group in $\alpha$-phenyl- $\alpha$-(pyridin-2yl)toluene, the relationship $\left.\right|^{2} J\left({ }^{1} \mathrm{H}-{ }^{199} \mathrm{Hg}\right) \mid=-2.96 \log K_{\mathrm{H}}+$ 241.6 Hz has been established, ${ }^{10}$ where $\log K_{\mathrm{H}}$ is the apparent protonation constant of the ligand determined in $50 \%$ dioxanewater. For polydentate pyridine donors, the coupling constant is higher than expected from this relationship if the ligand is coordinating as bidentate or tridentate. ${ }^{3.6 .11}$ For $[\mathrm{HgMe}$ (meso$\mathrm{L})]^{+}$and $[\mathrm{HgMe}(\mathrm{rac}-\mathrm{L})]^{+}$the coupling constant is $c a .25 \mathrm{~Hz}$
greater than expected for unidentate binding, involving the same nitrogen as occurs on protonation, and thus the complex(es) in solution involve polydentate co-ordination.

The chemical shift of the $\mathrm{Hg}^{11} \mathrm{Me}$ protons, -0.35 p.p.m., is further upfield than observed for any other complex ion $[\mathrm{HgMe}(\mathrm{L})]^{+}$, where L is a pyridine donor $(0.70-1.16$ p.p.m.), ${ }^{3.6 .11 .12}$ consistent with the presence of two phenyl groups in orientations resulting in anisotropic shielding of the methyl protons, e.g. as observed on comparison of spectra for $L=$ pyridine ( 1.08 p.p.m.) and 2-benzylpyridine ( 0.79 p.p.m.). ${ }^{11}$

Discussion.-The new tridentate ligand meso-L co-ordinates as a tripodal tridentate ligand to $\mathrm{Hg}^{\mathrm{II}} \mathrm{Me}$ and as a planar tridentate ligand to $\mathrm{Pd}^{\mathrm{II}}\left(\mathrm{O}_{2} \mathrm{CMe}\right){ }^{7}$ reflected most clearly in $\mathrm{N}(\mathrm{al})-\mathrm{M}-\mathrm{N}(\mathrm{cl})$ angles for the outer pyridine rings, 88.8(3) $(\mathbf{M}=\mathrm{Hg})$ and $177.8(2)^{\circ}(\mathrm{M}=\mathrm{Pd}) .^{7}$ As the ligand is flexible in its co-ordination mode, it would appear that $\mathrm{Hg}^{\text {II }} \mathrm{Me}$ prefers tripodal co-ordination. However, since palladium(II) has a strong preference for square-planar co-ordination, it is also possible that meso-L may be forced to adopt a less favoured conformation on binding to $\mathrm{Pd}^{\mathrm{II}}\left(\mathrm{O}_{2} \mathrm{CMe}\right)$, while $\mathrm{Hg}^{\mathrm{II}} \mathrm{Me}$, which is more flexible in its co-ordination behaviour and forms only weak secondary interactions with the outer pyridine donor groups, may accommodate a conformation preferred by the ligand.

The flexibility in co-ordination behaviour of the meso form of the ligand, the synthesis of the diastereoisomer mixture ( L ) in moderate yield ( $\mathrm{ca} .30 \%$ ) from 2-benzylpyridine, and the straightforward separation of meso-L and rac-L from their $\mathrm{Hg}^{\prime \prime}$ Me complexes, indicate that the new ligand may be of value to studies in co-ordination chemistry generally, e.g. as a pyridine analogue of tridentate diethylenetriamine and as a relative of planar $2,2^{\prime}: 6^{\prime}, 2^{\prime \prime}$-terpyridyl and tripodal tris(pyridin-2-yl)methane.

## Experimental

Microanalyses were by the Australian Microanalytical Service, i.r. spectra of complexes as Nujol and hexachlorobutadiene mulls ( $4000-400 \mathrm{~cm}^{-1}$ ) between KBr plates were measured with a Hitachi $270-30$ spectrophotometer. ${ }^{1} \mathrm{H}$ N.m.r. spectra in $\mathrm{CDCl}_{3}$ or $\mathrm{CD}_{3} \mathrm{OD}$ were measured with a Bruker AM-300 spectrometer, mass spectra were obtained with a VG MM $70-$ 70 F spectrometer, and the protonation constants of the tridentate ligand (in $50 \%$ dioxane-water) were measured under the conditions described earlier, ${ }^{10}$ using an automated equilibrium titrator with microcomputer implementations of MINIQUAD 75. ${ }^{13}$
Methylmercury(II) nitrate ${ }^{14}$ and 2-(1-phenylethyl)pyridine ${ }^{15}$ were prepared as described, 2,6-dichloropyridine was dried under vacuum over KOH , toluene and hexane were dried over $\mathrm{CaCl}_{2}$ followed by distillation from sodium and stored over sodium, bromobenzene was dried over $\mathrm{CaCl}_{2}$ followed by reflux and distillation over calcium turnings and storage over $4 \AA$ molecular sieves, dichloromethane was distilled, and diethyl ether was dried with a column of sieves followed by distillation over sodium-benzophenone and storage over sodium.

Preparation of 2,6-Bis[1-phenyl-1-(pyridin-2-yl)ethy] $]$ pyridine, L.-A deep red solution was obtained on addition of 2-(1phenylethyl)pyridine ( $2.604 \mathrm{~g}, 1.4 \mathrm{mmol}$ ) in diethyl ether ( 30 $\mathrm{cm}^{3}$ ) to a solution of phenyl-lithium [from lithium $(0.223 \mathrm{~g}, 3$ mmol ) and bromobenzene ( $1.64 \mathrm{~cm}^{3}, 1.6 \mathrm{mmol}$ ) in diethyl ether ( $30 \mathrm{~cm}^{3}$ )] under nitrogen. After stirring for $15 \mathrm{~min} \mathrm{2,6}$ dichloropyridine ( $1.053 \mathrm{~g}, 0.71 \mathrm{mmol}$ ) in diethyl ether ( $50 \mathrm{~cm}^{3}$ ) was added rapidly (dropwise), partly discharging the red colour with formation of a finely divided orange precipitate. Toluene ( $60 \mathrm{~cm}^{3}$ ) was added and diethyl ether removed by distillation.

The resulting suspension was refluxed for 20 h and, on cooling, the solution was hydrolysed with water ( $50 \mathrm{~cm}^{3}$ ) and acidified with $\mathrm{HCl}\left(5 \mathrm{~mol} \mathrm{dm}{ }^{-3}\right)$. After isolation and extraction of the aqueous phase with dichloromethane ( $20 \mathrm{~cm}^{3}$ ), the aqueous phase was neutralized with saturated $\mathrm{Na}_{2} \mathrm{CO}_{3}$. Dichloromethane extracts ( $3 \times 20 \mathrm{~cm}^{3}$ ) were combined, dried over magnesium sulphate, filtered, and reduced in volume under vacuum to give a pale yellow viscous oil. On standing the oil crystallized, and the crystals were recrystallized from diethyl ether-hexane to give colourless needles ( $0.932 \mathrm{~g}, 32 \%$ ), m.p. $96-$ $97^{\circ} \mathrm{C}$ (Found: C, 83.9; H, 6.3; N, 9.4. $\mathrm{C}_{31} \mathrm{H}_{27} \mathrm{~N}_{3}$ requires C, 84.3; $\mathrm{H}, 6.2 ; \mathrm{N}, 9.5 \%$ ); $v_{\text {max. }}$ at 1574 s br, $1494 \mathrm{~s}, 1470 \mathrm{~s}, 1444 \mathrm{~s}, 1428 \mathrm{~s}$, $1152 \mathrm{~m}, 1026 \mathrm{~m}, 992 \mathrm{~m}$ br, $788 \mathrm{~m}, 762 \mathrm{~m}, 748 \mathrm{~s}, 702 \mathrm{~s}, 630 \mathrm{~m}$ br, $594 \mathrm{~m}, 550 \mathrm{~m} \mathrm{~cm}^{-1}$. Mass spectrum: $m / e 441(M, 35 \%), 426(100)$, 260 (52), 259 (42), 183 (44), 182 (92), 181 (33), 180 (35), 168 (24), 167 (92), plus rings and their fragmentation ions. Potentiometric titration data were satisfactorily treated as arising from successive protonations of the ligand, with $\log K_{\mathrm{H}}$ for the equilibria calculated as 3.87 and 2.28 for successive protonations.

Synthesis of $[\mathrm{HgMe}(\mathrm{L})] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ Complexes.-A filtered solution of the ligand ( $1.433 \mathrm{~g}, 3.2 \mathrm{mmol}$ ) in acetone $\left(15 \mathrm{~cm}^{3}\right)$ was added to a filtered solution of methylmercury(II) nitrate ( $0.901 \mathrm{~g}, 3.2 \mathrm{mmol}$ ) in acetone ( $30 \mathrm{~cm}^{3}$ ). The solution was allowed to evaporate in a draught at ambient temperature to a volume of $c a .20 \mathrm{~cm}^{3}$ over a $2-3 \mathrm{~h}$ period, and colourless crystals of $\left[\mathrm{HgMe}(\right.$ meso-L) $] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ were collected and air dried ( 1.352 g ). The filtrate was transferred to a sealed chamber containing a beaker of diethyl ether, and on slow diffusion of ether vapour into the acetone solution two crops of $[\mathrm{HgMe}$ (racL) $] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ were obtained and combined ( $0.42 \mathrm{~g}, 13 \%$ ). The meso complex was recrystallized by dissolution in warm acetone ( $60 \mathrm{~cm}^{3}$ ) and evaporation to $c a .30 \mathrm{~cm}^{3}$ to give colourless crystals ( 0.494 g ). Further crops were obtained on continued volume reduction to give an overall yield of $1.087 \mathrm{~g}(44 \%)$.
$[\mathrm{HgMe}($ meso-L $)] \mathrm{NO}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. Found: C, $51.5 ; \mathrm{H}, 4.6 ; \mathrm{Hg}$, 27.9. $\mathrm{C}_{32} \mathrm{H}_{34} \mathrm{HgN}_{4} \mathrm{O}_{5}$ requires $\mathrm{C}, 50.9 ; \mathrm{H}, 4.5 ; \mathrm{Hg}, 26.7 \%$. Isolation of meso-L and rac-L from the $\mathrm{Hg}^{11} \mathrm{Me}$ Complexes.An identical procedure was used for both diastereoisomers, and the isolation of meso- L is given as an example. The $\mathrm{Hg}^{11} \mathrm{Me}$ complex ( $0.088 \mathrm{~g}, 0.12 \mathrm{mmol}$ ) was suspended in water ( $15 \mathrm{~cm}^{3}$ ) and sodium cyanide ( $0.0067 \mathrm{~g}, 0.14 \mathrm{mmol}$ ) was added with stirring. After stirring for 20 h the ligand was isolated by filtration using a fine sinter, washed with a large volume of water, dried in air, and then in a vacuum $(0.0447 \mathrm{~g}, 0.1 \mathrm{mmol}$, $86 \%$ ).
meso-L I.r. absorption: 3064 vw br, 2984 vw br, 1586 w and $1571 \mathrm{w}, 1496 \mathrm{w}, 1470 \mathrm{~m}, 1446 \mathrm{~m}, 1430 \mathrm{~m}, 1370 \mathrm{wbr}, 1206 \mathrm{vw}$ br,

rac-L I.r. absorption: 3060 vw br, 2996 w br, 1585 w and $1569 \mathrm{w}, 1496 \mathrm{w}, 1470 \mathrm{~m}, 1446 \mathrm{~m}, 1430 \mathrm{~m}, 1372 \mathrm{w}$ br, 1210 vw $\mathrm{br}, 1160 \mathrm{w}$ br, 1080 vw and $1068 \mathrm{vw}, 1026 \mathrm{w}, 992 \mathrm{vw}$ and 974 w $\mathrm{br}, 847 \mathrm{vw}, 816 \mathrm{vw}, 793 \mathrm{vw}, 771 \mathrm{w}, 744 \mathrm{w}, 700 \mathrm{w}, 646 \mathrm{vw}$ and 632 vw , and $551 \mathrm{vw} \mathrm{cm}{ }^{-1} .{ }^{1} \mathrm{H}$ N.m.r.: $8.54[\mathrm{~m}, 2 \mathrm{H}, J(5,6) 4.82 \mathrm{~Hz}$, $\mathrm{H}(6)$ (pyridines)], 7.54 (m, 2 H), 7.43 (m, 2 H ), $7.24-7.16$ (m, including intense peaks at $7.21,7.19,7.18,6 \mathrm{H}$ ), $7.1-7.08$ (m, $2 \mathrm{H}), 7.05(\mathrm{~m}, 2 \mathrm{H}), 7.02-6.43(\mathrm{~m}, 6 \mathrm{H})$, and $2.16\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{CH}_{3}\right)$.

Crystallography.-A unique data set was measured within the limit $2 \theta_{\text {max }}=50$ at $\sim 295 \mathrm{~K}$ using a Syntex $P \mathrm{~T}$ four-circle
diffractometer in conventional $2 \theta / \theta$ scan mode and using monochromatic Mo- $K_{\alpha}$ radiation $(\lambda=0.7106, ~ \AA$ ). 4111 Independent reflections were measured, 2600 with $I>3 \sigma(I)$ being considered 'observed' and used in the $9 \times 9$ blockdiagonal least-squares refinement after analytical absorption correction and solution of the structure by vector methods. Anisotropic thermal parameters were refined for the nonhydrogen atoms; $\left(x, y, z, U_{\text {iso }}\right)_{H}$ were included constrained at estimated values. Residuals on $|F|$ at convergence were $R=0.046 ; R^{\prime}=0.047\left[w=1 / \sigma^{2}(F)\right.$ derived from $\sigma^{2}(I)=$ $\left.\sigma_{\text {diff }}^{2}(I)+0.00042 \sigma^{4}{ }_{\text {diff }}(I)\right]$. Neutral complex scattering factors were used; ${ }^{16}$ computation used the XTAL 83 program system ${ }^{17}$ implemented by S.R. Hall on a Perkin-Elmer 3240 computer. Atomic co-ordinates are given in Table 2.

Crystal data. $\mathrm{C}_{32} \mathrm{H}_{34} \mathrm{HgN}_{4} \mathrm{O}_{5}, M=755.2$, monoclinic, space group $P 2_{1} / n\left(C_{2 h}{ }^{5}\right.$, no.14), $a=20.946(9), b=14.767(4), c=$ $9.817(3) \AA, \beta=91.12(2)^{\circ}, U=3036(1) \AA^{3}, D_{\mathrm{c}}(Z=4)=1.65$ $\mathrm{g} \mathrm{cm}{ }^{-3}, \quad F(000)=1496, \mu\left(\right.$ Mo- $\left.K_{x}\right)=49 \mathrm{~cm}^{-1}$. Specimen: $0.10 \times 0.35 \times 0.09 \mathrm{~mm} ; \mathrm{min}$. and max. transmission factors $=$ 1.43, 1.79. $T \sim 295 \mathrm{~K}$.

## Acknowledgements

We gratefully acknowledge support of this work by a grant from the Australian Research Grants Scheme, and assistance from Dr. A. P. Arnold with measurement of $\log K_{\mathbf{H}}$.
