# Crystal Structures and Properties of $\left[\mathrm{Au}(\mathrm{phen})\left\{(\mathrm{CN})_{0.92} \mathrm{Br}_{0.098}\right\}_{2}\right] \mathrm{Br}$ and [ Au (phen)(CN)\{(CN) $\left.\left.)_{0.82} \mathrm{Br}_{0.18}\right\}\right] \cdot 0.5$ trans $-\left[\mathrm{Au}(\mathrm{CN})_{2} \mathrm{Br}_{2}\right] \cdot 0.5 \mathrm{Br} \cdot \mathrm{phen}$ (phen $=1,10$-phenanthroline) $\dagger$ obtained by Disproportionation of Five-coordinate Bromodicyano(1,10-phenanthroline)gold(iII). Two Examples of Secondary Co-ordination and CN/Br Disorder in Square-planar Gold(iII) Complexes 

Giampaolo Marangoni * and Bruno Pitteri<br>Dipartimento di Chimica, Facoltà di Chimica Industriale, Università di Venezia, Calle Larga S. Marta 2137, 30123 Venezia, Italy<br>Valerio Bertolasi, Valeria Ferretti, and Gastone Gilli<br>Dipartimento di Chimica e Centro di Strutturistica Diffrattometrica, Università di Ferrara, Via Borsari 46, 44100 Ferrara, Italy

The disproportionation of neutral five-co-ordinate $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})_{2} \mathrm{Br}\right]$ (phen $=1,10$ phenanthroline) in dimethylformamide (dmf) gives a conducting solution from which two charged species, $\left[\mathrm{Au}(\mathrm{phen})\left\{(\mathrm{CN})_{0.92} \mathrm{Br}_{0.08}\right\}_{2}\right] \mathrm{Br}(1)$ and $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})\left\{(\mathrm{CN})_{0.82} \mathrm{Br}_{0.18}\right\}\right] \cdot 0.5$ trans$\left[\mathrm{Au}(\mathrm{CN})_{2} \mathrm{Br}_{2}\right] \cdot 0.5 \mathrm{Br}$-phen (2), have been separated and characterized by single-crystal $X$-ray analysis. Crystals of (1) are orthorhombic, space group Fmm2, $Z=4$ with $a=6.515$ (1), $b=11.76(2), c=18.666(2) \AA$. Crystals of (2) are triclinic, space group $P \overline{1}, Z=2$ with $a=9.149(3), b=9.263(3), c=15.485(5), \alpha=93.58(2), \beta=105.10(2), \gamma=95.49(2)^{\circ}$. The structures have been solved from three-dimensional counter data by Patterson and Fourier methods and refined by full-matrix least squares to $R 0.031$ and 0.044 for 729 and 2701 observed reflections respectively. The co-ordination of the cation in both compounds is square planar with two positions occupied by the two N atoms of the phenanthroline ligand. In compound (1) the other two cis positions are occupied by equivalent CN groups substituted in $8 \%$ of cases by Br . In compound (2) one position is occupied by a CN group and the other by a CN group in $82 \%$ and Br in $18 \%$ of cases. Secondary co-ordination is shown by both the complex cations with $\mathrm{Br}^{-}$at distances intermediate between bond and contact lengths, which gives rise to tetragonal bipyramidal and nearly square-pyramidal structures for (1) and (2) respectively.

Recently we re-examined the possibility of obtaining five-coordinate complexes of gold(iII) containing $\mathrm{N}-\mathrm{N}$ chelating ligands that were stable in the solid state and concluded that steric hindrance was not necessary if formation of the squareplanar chelate products could be prevented by having poor leaving groups in the substrate. On replacing $\left[\mathrm{AuBr}_{4}\right]^{-}$with the less substitutionally labile trans- $\left[\mathrm{Au}(\mathrm{CN})_{2} \mathrm{Br}_{2}\right]^{-}$we succeeded in obtaining the five-co-ordinate species bromodicyano( $1,10-$ phenanthroline)gold(iII), whose $X$-ray crystal structure showed it to be square pyramidal with the chelate spanning axial and equatorial sites and the two cyanides trans in the basal plane. ${ }^{1}$ This compound dissolves in dimethylformamide (dmf) to give a solution whose conductance is that of a non-electrolyte but which increases with time and two different crystalline species, (1) and (2), have been isolated under suitable conditions from the solutions. This paper reports their crystal structures and properties, together with a comparative study suggesting that secondary bonding is quite common in this class of squareplanar compounds.

## Experimental

Preparation of Complexes.-The complex [Au(phen)$\left.(\mathrm{CN})_{2} \mathrm{Br}\right] \cdot \mathrm{dmf}$ (phen $=1,10$-phenanthroline) was prepared as previously reported and its purity checked by its elemental analysis and i.r. spectrum. ${ }^{1}$

[^0]Compound $\left[\mathrm{Au}(\mathrm{phen})\left\{(\mathrm{CN})_{0.92} \mathrm{Br}_{0.08}\right\}_{2}\right] \mathrm{Br}$ (1). This was obtained on heating $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})_{2} \mathrm{Br}\right] \cdot \mathrm{dmf}(0.582 \mathrm{~g}, 1$ $\mathrm{mmol})$ in $\mathrm{dmf}\left(10 \mathrm{~cm}^{3}\right)$ at $50^{\circ} \mathrm{C}$ until constant conductance ( 1 h ) and then treating the resulting solution at room temperature according to one of the following procedures. (i) Water was added dropwise until the solution became cloudy. It was then left to crystallize overnight at $0^{\circ} \mathrm{C}$. Fine red crystals were obtained which were filtered off and dried under reduced pressure and used for $X$-ray structure determination. (ii) An equal volume of water was added to the solution and the yellow-orange microcrystalline precipitate immediately formed was separated, washed with water, methanol, and diethyl ether, and dried under reduced pressure. (iii) The solution was put aside to evaporate at room temperature whereupon red microcrystals slowly formed over a period of 10 d . They were collected and worked up as in (i).

The compounds from all the preparations show very similar i.r. spectra with regard to both the number and frequency of bands, with only minor differences in the relative peak height of the vibration at $260 \mathrm{~cm}^{-1}$, assignable to the $\mathrm{Au}-\mathrm{Br}$ stretching. Other characteristic bands fall at $2180[v(\mathrm{CN})], 464-475$ $[v(\mathrm{Au}-\mathrm{C})]$, and at $430 \mathrm{~cm}^{-1} \quad[\delta(\mathrm{Au}-\mathrm{C}-\mathrm{N})]$. A series of elemental analyses carried out on crystals obtained from several preparations following method (i) gave analytical figures which indicate a variable composition due to isomorphous replacement of CN by Br , in the range $7-18 \%$, as referred to a stoicheiometric species $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})_{2}\right] \mathrm{Br}, \mathrm{C}_{14} \mathrm{H}_{8} \mathrm{AuBrN}_{4}$ [Found: (a) C, 32.8; H, 1.55; Br, 16.7; N, 10.8. (b) C, 31.6; H, 1.50; $\mathrm{Br}, 18.0 ; \mathrm{N}, 10.2 . \mathrm{C}_{14} \mathrm{H}_{8} \mathrm{AuBrN}_{4}$ requires $\mathrm{C}, 33.0 ; \mathrm{H}, 1.55 ; \mathrm{Br}$,
$15.7 ; \mathrm{N}, 11.0 \%$ ]. The single crystal for the $X$-ray structure determination of (1) was chosen from the product analyzed as in (b).

Compound $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})\left\{(\mathrm{CN})_{0.82} \mathrm{Br}_{0.18}\right\}\right] \cdot 0.5$ trans- $[\mathrm{Au}-$ $\left.(\mathrm{CN})_{2} \mathrm{Br}_{2}\right] \cdot 0.5 \mathrm{Br}$-phen (2). To a solution of $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})_{2}-\right.$ $\mathrm{Br}] \cdot \operatorname{dmf}(0.582 \mathrm{~g}, 1 \mathrm{mmol})$ in $\operatorname{dmf}\left(10 \mathrm{~cm}^{3}\right)$ brought to constant conductance ( $50^{\circ} \mathrm{C}, 1 \mathrm{~h}$ ), diethyl ether was added at room temperature until incipient clouding occurred, and the resulting solution was left overnight at $-10^{\circ} \mathrm{C}$. The crystalline product formed was filtered off and dried under reduced pressure. A microscopic observation revealed that it was a mixture of two well separated types of crystals of different colour and shape. The red ones were shown to be compound (1) by their i.r. spectrum and analysis, while the orange fraction, present in a small quantity, did not allow proper physicochemical determinations. A well formed crystal was then chosen and its $X$-ray structure solved.

Infrared spectra ( $4000-600 \mathrm{~cm}^{-1}, \mathrm{KBr}$ discs and Nujol mulls; $600-200 \mathrm{~cm}^{-1}$, polyethylene dispersions) were recorded with a Perkin-Elmer 683 spectrophotometer. Conductance measurements were carried out with a CDM 83 Radiometer Copenhagen conductivity meter and CDC 334 immersion electrode.

Crystal Structure Determination of Compound (1).-Intensity data were collected on an Enraf-Nonius CAD4 diffractometer with monochromated Mo- $K_{\alpha}$ radiation and $\omega-2 \theta$ scan technique. Cell parameters were obtained from least-squares refinement of the setting angles of 25 centred reflections in the range $10 \leqslant \theta \leqslant 14^{\circ}$. Crystal data are reported in Table 1. Intensities were corrected for Lorentz polarization and absorption (minimum transmission factor, $64.7 \%$ ). Scattering factors and anomalous dispersion parameters were taken from ref. 2.

| Weighting scheme ( $1 / w$ ) | $1 /\left[\sigma^{2}(I)+0.05(I)\right]$ | $1 /\left[\sigma^{2}(I)+0.06(I)\right]$ |
| $S=$ Error in an observation of unit weight | 1.11 | 1.08 |

${ }^{a}$ Data common to both determinations: graphite-monochromated Mo- $K_{\alpha}$ radiation $\lambda=0.71069 \AA, T=22^{\circ} \mathrm{C}$; three standard reflections. ${ }^{b} R=\Sigma\left|\Delta F_{0}\right| / \Sigma\left|F_{0}\right| ; R^{\prime}=\left(\Sigma \omega\left|\Delta F_{0}\right|^{2} / \Sigma w\left|F_{0}\right|^{2}\right)^{\frac{1}{2}}$.

The structure was solved by Patterson and Fourier methods. Anomalies in the Fourier difference map and in the Au-C and $\mathrm{C}-\mathrm{N}$ distances were indicative of some disorder in the CN region. Accurate refinement by trial and error showed the presence of $8 \%$ of Br substituting the CN groups. Hydrogen atoms were given calculated positions with $\mathrm{C}-\mathrm{H} 0.95 \AA$ and fixed isotropic thermal parameters of $5.0 \AA^{2}$. After a few cycles of isotropic refinement the structure was refined by full-matrix least squares using anisotropic thermal parameters for all nonhydrogen atoms. Weights for the last cycle were applied according to the scheme given in Table 1. The $\mathrm{Br}: \mathrm{CN}$ occupancy ratio for disordered positions was determined to be 0.087 by carrying out several refinements and choosing that giving the lowest $R$ and the best set of distances. As the space group was chiral, two independent refinements were carried out on the enantiomeric structures. The data presented refer to the structure with the lowest $R$ value (for reference, $R_{1}$ and $R_{2}$ for the opposite choice of axes were 0.034 and 0.042 respectively). All calculations were performed by the SDP system of programs. ${ }^{3}$ Final positional parameters ${ }^{4}$ are given in Table 2.

Crystal Structure Determination of Compound (2).-Intensity data and cell parameters ( 22 reflections in the range $10 \leqslant \theta \leqslant$ $14^{\circ}$ ) were obtained by the procedure given for compound (1). Intensities were corrected for Lorentz polarization and absorption (minimum transmission factor, 48.6\%). Crystal data are reported in Table 1.

The positions of the gold atoms and $\operatorname{Br}(2)$ were located from Patterson syntheses. All other non-hydrogen atoms were found in the subsequent Fourier maps. Anomalies in the Fourier difference map and in the $\mathrm{Au}(2)-\mathrm{C}(3)$ and $\mathrm{C}(3)-\mathrm{N}(3)$ distances were indicative of some disorder in the $\mathrm{C}(3)-\mathrm{N}(3)$ region. Hydrogen atoms were given calculated positions with C-H 0.95 $\AA$ and fixed isotropic thermal parameters of $5.0 \AA^{2}$. After a few cycles of isotropic refinement the structure was refined by fullmatrix least squares using anisotropic thermal parameters for all non-hydrogen atoms. Weights for the last cycle were applied according to the scheme given in Table 1. The $\operatorname{Br}(3): C(3)-N(3)$ occupancy ratio in the disordered positions was determined to be 0.22 by the method reported for compound (1). Final positional parameters ${ }^{4}$ are given in Table 3.

## Results and Discussion

The five-co-ordinate square-pyramidal bromodicyano(1,10phenanthroline)gold(iii) complex dissolves readily in dmf giving a yellow solution whose initial conductance is that of a non-electrolyte, but it increases with time reaching a final value

Figure 1. An ORTEP view of $\left[\mathrm{Au}(\mathrm{phen})\left\{(\mathrm{CN})_{0.92} \mathrm{Br}_{0.08}\right\}_{2}\right] \mathrm{Br}$ (1) showing thermal ellipsoids at $40 \%$ probability
(33-38 $\mathrm{ohm}^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$ ) only about half of that expected for a $1: 1$ electrolyte ( $65-90 \mathrm{ohm}^{-1} \mathrm{~cm}^{2} \mathrm{~mol}^{-1}$ ). ${ }^{5}$ Consequently, a simple dissociation $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})_{2} \mathrm{Br}\right] \longrightarrow[\mathrm{Au}($ phen $)-$ $\left.(\mathrm{CN})_{2}\right]^{+}+\mathrm{Br}^{-}$can be ruled out. It seems, therefore, more likely that the complex disproportionates in much the same way as the $\left[\mathrm{Au}(\mathrm{N}-\mathrm{N}) \mathrm{X}_{3}\right]$ analogues ( $\mathrm{N}-\mathrm{N}=$ phen or $2,2^{\prime}$-bipyridyl; $\mathrm{X}=\mathrm{Cl}$ or Br ). ${ }^{6,7}$ Harris ${ }^{6,7}$ showed quite convincingly that solutions of $\left[\mathrm{Au}(\mathrm{N}-\mathrm{N}) \mathrm{X}_{3}\right]$ in nitrobenzene, nitromethane, and acetone led immediately to disproportionation [equation (1)].

$$
2\left[\mathrm{Au}(\mathrm{~N}-\mathrm{N}) \mathrm{X}_{3}\right] \underset{\left[\mathrm{Au}(\mathrm{~N}-\mathrm{N}) \mathrm{X}_{2}\right]^{+}+\left[\mathrm{AuX}_{4}\right]^{-}+\mathrm{N}-\mathrm{N}}{\rightleftharpoons}
$$

In this way the conductance results are readily explained and the final electronic spectrum could be reproduced exactly by adding equal contributions of $\left[\mathrm{Au}(\mathrm{N}-\mathrm{N}) \mathrm{X}_{2}\right] \mathrm{ClO}_{4},\left[\mathrm{NEt}_{4}\right]$ [ $\mathrm{AuX}_{4}$ ], and $\mathrm{N}-\mathrm{N}$.
In the case of $\left[\mathrm{Au}(\mathrm{phen})(\mathrm{CN})_{2} \mathrm{Br}\right]$ the main difference lies in the slowness of the disproportionation, and the nature of the solid products (1) and (2) isolated from the solution is less obvious. ORTEP ${ }^{8}$ views for compounds (1) and (2) are shown

Figure 2. An ORTEP view of $\left[\mathrm{Au}(\right.$ phen $\left.)(\mathrm{CN})\left\{(\mathrm{CN})_{0.82} \mathrm{Br}_{0.18}\right\}\right]$ 0.5 trans $-\left[\mathrm{Au}(\mathrm{CN})_{2} \mathrm{Br}_{2}\right] \cdot 0.5 \mathrm{Br} \cdot$ phen (2) showing thermal ellipsoids at 40\% probability
in Figures 1 and 2 respectively. Bond distances and angles are reported in Tables 4 and 5 for (1) and (2) respectively.

Crystal (1) consists of $\left[\mathrm{Au}(\mathrm{phen})\left\{(\mathrm{CN})_{0.92} \mathrm{Br}_{0.08}\right\}_{2}\right]^{+}$cations in $m m$ crystallographic symmetry positions with the Au atom at $0,0, z$ (one $m$ containing all the cation) and $\mathrm{Br}^{-}$anions on mm crossing at $\frac{1}{2}, 0, z$. The gold co-ordination is square planar for symmetry. The phenanthroline ligand is cut by the other symmetry plane, and the two symmetry-equivalent CN groups
are substituted in $8 \%$ of cases by Br . The $\mathrm{Au}-\mathrm{CN}$ and $\mathrm{Au}-\mathrm{N}$ distances are 1.92(1) and 2.14(1) $\AA$ respectively. Two $\mathrm{Br}^{-}$anions are octahedrally co-ordinated at a distance of $3.277(1) \AA$, which is intermediate between bond and contact lengths. The $\mathrm{Au}-\mathrm{Br}$ line makes an angle of $6.20(3)^{\circ}$ with the normal to the basal plane and is slightly bent towards the phenanthroline side. Each $\mathrm{Br}^{-}$is shared by two gold(III) cations leading to a chain structure of octahedra.
Crystal (2) is built up of $\left[\mathrm{Au}(\text { phen })(\mathrm{CN})\left\{(\mathrm{CN})_{0.82} \mathrm{Br}_{0.18}\right\}\right]^{+}$ cations in general positions, trans- $\left[\mathrm{Au}(\mathrm{CN})_{2} \mathrm{Br}_{2}\right]^{-}$anions lying on symmetry centres at $0,0,0, \mathrm{Br}^{-}$ions on symmetry centres at $0,0, \frac{1}{2}$, and free phenanthroline molecules in general positions. The cation displays a square-planar co-ordination with two cis positions occupied by the two N atoms of the phenanthroline ligand at a distance of 2.05(1) and 2.02(1) $\AA$. Another position is occupied by a CN group and the last one by a CN group in

$82 \%$ and Br in $18 \%$ of cases. The phenanthroline ligand is substantially planar, the angles between adjacent six-membered rings being $0.7(4)$ and $1.9(4)^{\circ}$. Bond distances and angles in the ligand are similar to those of the free molecule and match perfectly the data of previous structures. ${ }^{1,9}$ The first coordination atoms define a plane ( $\chi^{2}=10.8$ ) from which the Au atom is displaced by $0.022 \AA^{2}$ toward a fifth $\mathrm{Br}^{-}$ligand, expanding the co-ordination to square pyramidal; each $\mathrm{Br}^{-}$ links two cations forming a dimer of two pyramids sharing the apical vertex. However, the $\mathrm{Br}^{-}$is at a distance of 3.165(1) $\AA$ from $\mathrm{Au}{ }^{\text {III }}$ which is intermediate between the $\mathrm{Au}-\mathrm{Br}$ bond ( $2.43 \AA$ ) and van der Waals contact distance ( $4.09 \AA$ ). The $\mathrm{Au}-\mathrm{Br}$ line makes an angle of $14.7(2)^{\circ}$ with the normal to the basal plane. The $\mathrm{Au}-\mathrm{CN}$ distance for the non-disordered ligand is $2.03(1) \AA$, similar to those of $2.004(6)$ and $1.986(6) \AA$ previously determined. ${ }^{1}$ The anion is perfectly planar for symmetry and $\mathrm{Au}-\mathrm{Br}$ and $\mathrm{Au}-\mathrm{CN}$ distances are 2.431(2) and 2.02(2) $\AA$ respectively.

The most striking feature of both (1) and (2) is their ability to form secondary bonds with $\mathrm{Br}^{-}$anions outside the squareplanar (s.q.) co-ordination although in different ways. In (1) the co-ordination is nearly octahedral, or better, tetragonal bipyramidal (t.b.p.), and in (2) nearly square pyramidal (s.p.). We have investigated the occurrence of such a feature in gold(III) square-planar complexes (the search was carried out on the Cambridge Crystallographic Data Base ${ }^{10}$ ). Of 102 entries nearly $15 \%$ were found to display secondary co-ordination and the compounds involved are listed in Table 6.
Two different situations can be identified. T.b.p.co-ordination is mostly achieved by intermolecular contacts with two single ions, typically $\mathrm{Cl}^{-}, \mathrm{ClO}_{4}^{-}, \mathrm{I}^{-}, \mathrm{Br}^{-}$, or neutral O atoms ( $\mathrm{R}-\mathrm{OH}$ or pyridine $N$-oxide) while six-co-ordination caused by intramolecular contacts is rare owing to the difficulty ligands have in matching the geometrical constraints. In two cases six-coordination is achieved by the use of Cl and S as equatorial ligands (entries 14 and 16 of Table 6).

On the contrary, s.p. five-co-ordination is usually observed with multidentate ligands having a position free for further

apical pyramidal co-ordination, in which case the pyramid is remarkably distorted owing to the small ligand bite.
The majority of both s.p. and t.b.p. complexes are observed as $\mathrm{AuL}_{4} \cdots \mathrm{X}$ or $\mathrm{X} \cdots \mathrm{AuL}_{4} \cdots \mathrm{X}$ monomeric molecular units inside the crystals. Exceptions are pyramidal dimers $\mathrm{AuL}_{4} \cdots \mathrm{Br}^{\prime} \cdots \mathrm{AuL}_{4}$, entry 2 of Table 6, and bipyramidal
 with $\mathrm{X}=\mathrm{ClO}_{4}^{-}$(entry 12) or $\mathrm{Br}^{-}$(entry 17). Sometimes these chains are obtained by interlinking intramolecular pyramids by the use of an equatorial shared ligand (entries 14 and 16). In one case (entry 15), finally, bipyramids are linked in chains by $\mathrm{OH} \ldots \mathrm{O}$ hydrogen bonds. In Figure 3 are shown sketches of the observed secondary co-ordination schemes of these gold(III) complexes. The scarce occurrence of infinite chains seems to indicate that secondary co-ordination is not necessarily related to the increase in Madelung energy of the one-dimensional ( -+-+ ) lattice, but mostly to a simple single anion-gold(III) interaction.

Table 6 reports the observed $\mathrm{Au} \ldots \mathrm{X}$ distances for secondary co-ordination. As the figures refer to different situations we thought it worthwhile to reduce all distances to the equivalent $\mathrm{Au} \cdots \mathrm{Br}$ ones assuming covalent radii of 0.75 for $\mathrm{N}, 0.74$ for O , 1.04 for $\mathrm{S}, 1.00$ for $\mathrm{Cl}, 1.14$ for Br , and $1.35 \AA$ for $\mathrm{I} .^{11}$ Such equivalent distances are shown in the fourth column of Table 6 and plotted in Figure $4(a)$ and (b).

Figure 4(a) shows that the added apical ligand is bound at a distance which is intermediate between bond and van der Waals lengths; shortest distances in the range $2.97-3.16 \AA$ corresponding to intramolecular contacts (entries 1,3-5), the two $\mathrm{Cl}^{-}$and $\mathrm{Br}^{-}$contacts (entries 6 and 9) being slightly longer ( 3.15 and $3.16 \AA$ ). The two inter- and intra-molecular distances at 3.47 and $3.53 \AA$ correspond to situations of much weaker interaction. Comparison of $\mathrm{Au}-\mathrm{X}$ bond distances in the squareplanar moiety shows that the entering apical ligand is able to displace the Au atom from the basal plane (towards the ligand) by up to $0.118 \AA$ but not significantly to lengthen the basal $\mathrm{Au}-\mathrm{X}_{\mathrm{eq}}$ bonds. The two $\mathrm{Au}-\mathrm{X}_{\mathrm{eq}}$ bond length distributions (one with and the other without the apical bond) are practically coincident, the main scattering factor being connected with the usual trans influence in this class of compounds.

Figure $4(b)$ shows a scatterplot of the two equivalent $\mathrm{Au} \cdots \mathrm{Br}$ secondary trans-co-ordination distances for t.b.p. compounds. It shows that the two distances increase together, indicating that the entering of a sixth apical substituent cannot be considered a nucleophilic addition trans to the other apical group. In such a case, lengthening of the apical ligand bond with progressive approaching of the trans ligand would have been observed. Conversely, the present plot is more consistent with rehybridization of the central atom from s.p. $d s p^{3}$ to t.b.p., nearly $d^{2} s p^{3}$. As for Au-X bond distances in the square-planar

Figure 3. Sketches of the observed secondary co-ordination schemes of square-planar gold(III) complexes; s.p. 1-s.p. 3 and t.b.p. 1-t.b.p. 5 as in the third column of Table 6

Figure 4. (a) Histogram of equivalent $\mathrm{Au} \cdots \mathrm{Br}$ secondary coordination distances for the square-pyramidal compounds of Table 6. (b) Scatterplot of the two equivalent $\mathrm{Au} \cdots \mathrm{Br}$ secondary trans coordination distances for octahedral compounds of Table 6. In both cases the bond and contact $\mathrm{Au} \cdot \mathrm{Br}$ distances are assumed to be 2.43 and $4.09 \AA$ respectively. Numbers refer to the compounds in Table 6
basal plane, considerations similar to those for pyramidal coordination hold. On the other hand, it is reasonable that no lengthening of the short (strong) equatorial bonds is observed, since the mathematical form of the relationship between bond lengths of the entering (axial) and leaving (equatorial) group is logarithmic ${ }^{12}$ allowing the relevant approach of the new ligand without any significant lengthening of the old bond.

All the phenomena of secondary co-ordination can be interpreted by saying that $10 D q$ is relevant for $d^{8}$ gold(III) complexes owing to both its high oxidation number and its position in the third transition series, so that high-spin octahedral complexes cannot be achieved, while low spin s.p. and t.b.p. geometries are easily obtained by perturbation of low-spin square-planar complexes.

The general situation is that of three different geometries which can in some way be permutated according to the most favourable packing conditions. Such reasoning can, however, be extended to take into account complex equilibria in solution among the different species, though with different populations. These agree with the suggestion that high-co-ordination species have been found in solution on the grounds of kinetic studies ${ }^{13}$ and can be taken as a warning that both the thermodynamic and kinetic behaviour of gold(III) complexes may be much more complicated than is usually believed.
