# Synthesis and Crystal Structure of New Polynuclear Rhodium Complexes formed by Reaction of Bis( $\eta$-ethylene) ( $\eta^{5}$-indenyl)rhodium with t-Butylphospha-acetylene $\dagger$ 

Paul Binger,* Bruno Biedenbach, Richard Mynott, Reinhard Benn, Anna Rufińska, Peter Betz, and Carl Krüger<br>Max-Planck-Institut für Kohlenforschung, D-4330 Mülheim a. d. Ruhr, Germany

#### Abstract

Treatment of bis $\left(\eta\right.$-ethylene) ( $\eta^{5}$-indenyl)rhodium (1) or (cyclo-octa-1,5-diene) ( $\eta^{5}$-indenyl)rhodium (2) with t-butylphospha-acetylene (3) yields [ $\eta^{4}-2,4$-di(t-butyl)-1,3-diphosphacyclobutadiene] ( $\eta^{5}$ indenyl)rhodium (4) as the main product together with two other rhodium complexes (5) and (6) that contain derivatives of the new ligated systems 1,2,4,5-tetraphosphabenzenediyl and 1 -rhoda-2,5-diphosphacyclopentenediyl, respectively. Phosphorus-31, ${ }^{1} \mathrm{H}$, and ${ }^{13} \mathrm{C}$ n.m.r. data are reported and are discussed in relation to the structures, which in the case of (5) and (6) were established by $X$-ray diffraction analyses. The n.m.r. spectra of (6) reveal restricted rotation of one of the indenyl groups.

$\eta^{4}$-1,3-Diphosphacyclobutadiene complexes of cobalt, ${ }^{1-3}$ rhodium, ${ }^{3}$ and iridium ${ }^{3}$ are now readily available from the reaction of compounds of the type $\left[M\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{5}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]$ ( $\mathrm{R}=\mathrm{H}, \mathrm{M}=\mathrm{Co}$ or $\mathrm{Rh} ; \mathrm{R}=\mathrm{Me}, \mathrm{M}=\mathrm{Co}, \mathrm{Rh}$, or Ir) or [Co-$\left.\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]\left(\mathrm{C}_{9} \mathrm{H}_{7}=\right.$ indenyl) with t -butylphosphaacetylene (3) or isopropylphospha-acetylene.

While the yields of the $\eta^{4}$-1,3-diphosphacyclobutadiene cobalt complexes are good, despite the fact that they are able to form di- and tri-nuclear adducts with the starting material $\left[\mathrm{Co}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]$ by interaction with the lone pairs of the two phosphorus atoms of the diphosphacyclobutadiene ring, ${ }^{1,2}$ the yields of the corresponding rhodium and iridium complexes are disappointingly low. ${ }^{3} \mathrm{Di}$ - and tri-nuclear rhodium complexes analogous to those produced by the reaction of (3) with [Co( $\left.\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}$ ] are obviously not formed, even though such kinds of interaction have been found when [ $\{\mathrm{RhCl}-$ $\left.\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right\}_{2}$ ] is used as the starting material. ${ }^{4}$ We therefore undertook a study of the reactions of $\left[\mathrm{Rh}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]$ (1) and $\left[\mathrm{Rh}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)(\right.$ cod $\left.)\right]$ (2) (cod $=$ cyclo-octa-1,5-diene) with $t$-butylphospha-acetylene to endeavour to isolate and characterize those rhodium complexes besides [ $\eta^{4}-2,4-\mathrm{di}(\mathrm{t}-$ butyl)-1,3-diphosphacyclobutadiene] $\left(\eta^{5}\right.$-indenyl)rhodium (4) that are formed in this reaction. The results of this study are presented herein.

## Results and Discussion

The reaction between complex (1) and a two-fold excess of (3) in diethyl ether is complete after 5 h at $0^{\circ} \mathrm{C}$ and affords three isolable rhodium complexes (4)-(6) (Scheme 1), in an overall yield of $46 \%$. The red crystalline trinuclear complex (6) is obtained directly in $13 \%$ yield by filtration of the reaction mixture while (4) and (5) must be separated chromatographically. On $\mathrm{Al}_{2} \mathrm{O}_{3}$ and with toluene as eluant, complex (4) is separated first and is obtained as yellow crystals in $30 \%$ yield. The second fraction contains the pure complex (5), which is isolated in $3 \%$ yield as red crystals. When the rhodium complex (2) is taken as starting material the overall yield is $69 \%$ and only the complexes (4) and (6) are obtained (yield 36 and $33 \%$, respectively).

Complex (4) was readily identified as [ $\eta^{4}-2,4-$ di(t-butyl)-1,3diphosphacyclobutadiene] ( $\eta^{5}$-indenyl)rhodium by comparison of its spectroscopic data with those of known 1,3-diphosphacyclobutadiene complexes of cobalt and rhodium. ${ }^{1-3}$ Its
elemental analysis also agrees with this formulation (see Experimental section). In its ${ }^{31} \mathrm{P}$ n.m.r. spectrum just one signal is observed, a doublet at 45.6 p.p.m. [ $\left.{ }^{1} J(\mathrm{RhP})=31.3 \mathrm{~Hz}\right]$, in agreement with corresponding data for known (1,3-diphosphacyclobutadiene)rhodium complexes. ${ }^{3}$ The signal of the $1,3-$ diphosphacyclobutadiene ring carbon is observed at $\delta 112.7$ $\left[{ }^{1} J(\mathrm{PC})=56.0, J(\mathrm{RhC})=15.1 \mathrm{~Hz}\right]$. The ${ }^{103} \mathrm{Rh}$ chemical shift is -10216 p.p.m. ${ }^{5}$ \{relative to external $\left[\mathrm{Rh}(\mathrm{acac})_{3}\right]$ (acac $=$ acetylacetonate) Table 5\} and thus close to that for $\left[\mathrm{Rh}\left(\eta^{5}\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\eta^{4}-\mathrm{C}_{4} \mathrm{H}_{4}\right)\right], \delta\left({ }^{103} \mathrm{Rh}\right)-10415$ p.p.m. ${ }^{6}$

The ${ }^{31} \mathrm{P},{ }^{103} \mathrm{Rh}$, and ${ }^{13} \mathrm{C}$ n.m.r. spectra of (6) showed that the compound is pure and is a trinuclear species; at $40^{\circ} \mathrm{C}$ some signals were broadened, indicating that dynamic behaviour is present. However, these spectra as well as the ${ }^{31} \mathrm{P}$ n.m.r. spectrum of (5) were too complicated to determine the structures directly because of the large number of magnetically active nuclei that couple with one another. Therefore $X$-ray diffraction studies of the complexes (5) and (6) were carried out.

Perspective views of the molecules (5) and (6) are shown in Figures 1 and 2, respectively; atomic co-ordinates and relevant bond lengths and angles are summarized in Tables 1-4. The most striking feature of (5) is the novel ligated $3,6-\mathrm{t}$-butyl-1,2,4,5-tetraphosphabenzenediyl heterocyclic ring, which must stem from four t-butyl phospha-acetylenes, with loss of one di-(t-butyl)acetylene; this di(t-butyl)acetylene was detected in the reaction mixture by g.c. analysis. The six-membered ring is located between the two rhodium atoms and consists of two $\mathrm{CP}_{2}$ subunits, the planes of which are twisted with respect to each other by $49.8^{\circ}$. Each subunit is $\eta^{3}$-co-ordinated to one metal atom and interacts with the other one via an additional Rh-P bond. The C-P bond lengths all lie within $1.77-1.81 \AA$, which is in the range for $\eta^{3}$-1,3-diphospha-allyl metal systems ${ }^{7}$ but the bond between $\mathrm{P}(1)$ and $\mathrm{P}(3)[2.445(1) \AA]$ is considerably longer than that between $P(2)$ and $P(4)[2.238(1) \AA]$. However, the observation of $J(\mathrm{PP})=204 \mathrm{~Hz}$ between $\mathrm{P}(1)$ and $\mathrm{P}(3)$ confirms that they must be bonded to one another. In addition each rhodium atom has a $\eta^{5}$-bonded indenyl ligand.

As in (5), each rhodium atom in the trinuclear complex (6) is connected to an indenyl group, but different $\mathrm{Rh}-\mathrm{C}$ distances suggest that the co-ordination is better described as $\eta^{3}$ bonding. Atom $\mathrm{Rh}(1)$ is part of a 1 -metalla-2,5-diphosphacyclopent-

[^0]

Scheme 1. $(i)+\mathrm{P} \equiv \mathrm{CBu}^{\mathrm{t}}$; $(i i)-\mathrm{Bu}^{\mathrm{t}} \mathrm{C} \equiv \mathrm{CBu}^{\mathrm{t}}$
enediyl ring. It is bent out of the plane defined by the $\mathrm{C}_{2} \mathrm{P}_{2}$ fragment of the ring by $50.6^{\circ}$. The $\mathrm{C}_{2} \mathrm{P}_{2}$ fragment of this heterocycle is $\eta^{4}$-co-ordinated to $\mathrm{Rh}(2)$ such that $\mathrm{Rh}(1)$ and $\mathrm{Rh}(2)$ belong to a four-membered $\mathrm{Rh}_{2} \mathrm{P}_{2}$ ring with an angle of $16.8^{\circ}$ between the two $\mathrm{RhP}_{2}$ planes. The distance of $1.416(6) \AA$ between $\mathrm{C}(1)$ and $\mathrm{C}(6)$ is typical for a $\pi$-bonded $\mathrm{C}=\mathrm{C}$ double bond, while the distances $\mathrm{C}(1)-\mathrm{P}(1)[1.828(4) \AA]$ and $\mathrm{C}(6)-\mathrm{P}(2)$ $[1.843(4) \AA$ ] are somewhat shorter than normal P-C single bonds. No bonding interaction exists between $\mathrm{P}(1)$ and $\mathrm{P}(2)$ $\left[P(1) \cdots P(2) ; 2.549(2) \AA\right.$, see discussion of the ${ }^{31} \mathrm{P}$ n.m.r. spectrum]. This part of the molecule is similar to a dirhodium complex, $\left[\mathrm{Rh}_{2}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{4} \mathrm{Et}\right)_{2}\left(\eta^{4}-\mathrm{P}_{4}\right)(\mathrm{CO})\right]$, in which a rhodatetraphosphacyclopentadiene is $\eta^{4}$-bonded to the second rhodium. ${ }^{8}$ Atom $\mathrm{Rh}(3)$ is part of a fragment similar to the mononuclear [2,4-di(t-butyl)-1,3-diphosphacyclobutadiene]indenylcobalt complex ${ }^{2}$ or complex (4). This fragment contains an approximately planar 1,3 -diphosphacyclobutadiene ring, which is $\eta^{4}$-bonded to $\mathrm{Rh}(3)$ and connected to the rest of the molecule via a $\sigma$-donor- $\pi$-acceptor interaction between $\mathrm{P}(3)$ and $\operatorname{Rh}(1)$.
The n.m.r. spectra of complex (6) in solution are consistent with the structure found in the solid. The ${ }^{103} \mathrm{Rh}$ n.m.r. spectrum indicates directly a trinuclear complex. One of the signals (Table 5 ) is found at -10392 p.p.m., suggesting that one of the ( $\eta^{5}$ -
indenyl)rhodium moieties is $\eta^{4}$-bonded to a phosphacyclobutadiene ring. Several $J(\mathrm{RhP})$ coupling constants were identified, thus simplifying the interpretation of the ${ }^{31} \mathrm{P}$ n.m.r. spectra.

The detailed analysis of the ${ }^{31} \mathrm{P}$ n.m.r. spectrum of complex (6) also requires comparison of the spectra recorded at -80 and $+40^{\circ} \mathrm{C}$ [the couplings to $\mathrm{P}(1)$ and $\mathrm{P}(2)$ become averaged] (Table 6). At $-80^{\circ} \mathrm{C}$ four signals are observed at $\delta 3.1[\mathrm{P}(4)]$, $88.4[\mathrm{P}(3)], 83.1$ and 115.7 p.p.m. [P(1) and P(2)]. Examination of the spectra shows that two of the phosphorus atoms do not undergo exchange. Their data are consistent with $P(3)$ and $P(4)$ (numbering in Figure 2) in the 1,3-diphosphacyclobutadiene ring; $P(3)$ is identified by the large coupling to the $\sigma$-bonded rhodium atom $\mathrm{Rh}(1)(228 \mathrm{~Hz})$. The phosphorus atoms resonating at 115.7 and 83.1 p.p.m. undergo exchange with one another, such that at $40^{\circ} \mathrm{C}$ a very broad signal $\left(\Delta v_{\frac{1}{f}} c a .1000\right.$ Hz ) is observed at 91 p.p.m. At $-80^{\circ} \mathrm{C}$ the coupling constant $J[\mathrm{P}(1), \mathrm{P}(2)]$ is unresolved and must be less than 5 Hz , confirming that $\mathrm{P}(1)$ is not bonded to $\mathrm{P}(2)$. Interestingly, the coupling constants between $\mathrm{P}(1), \mathrm{P}(2)$, and $\mathrm{Rh}(1)(48$ and 42 Hz$)$ are only slightly greater than those to $\mathrm{Rh}(2)$.

In the ${ }^{13} \mathrm{C}$ n.m.r. spectrum at $-80^{\circ} \mathrm{C}$ all the carbon atoms (except the methyl carbons of the t-butyl groups) are inequivalent. At $40^{\circ} \mathrm{C}$ the signals have coalesced pairwise with the
exception of those from the 2 position of the indenyl groups. Atoms $\mathrm{C}(11)$ and $\mathrm{C}(16)$ in the 1,3 -diphosphacyclobutadiene ring ( $-80^{\circ} \mathrm{C}, 108.7$ and $107.5: 40^{\circ} \mathrm{C}, 109.1$ p.p.m.) are easily identified by the similarity of their chemical shifts and coupling constants with those of related systems ${ }^{2}\left\{{ }^{1} J[\mathrm{P}(4) \mathrm{C}]=60\right.$, ${ }^{1} J[\mathrm{P}(3) \mathrm{C}]=15 \mathrm{~Hz}$ [the lone pair of $\mathrm{P}(3)$ is donated to a further atom] $\}$. Atoms $\mathrm{C}(1)$ and $\mathrm{C}(6)\left(-80^{\circ} \mathrm{C}, 122.1\right.$ and 121.7; $40^{\circ} \mathrm{C}, 121.5$ p.p.m.) are distinguished from the remaining signals from quaternary carbons by the large coupling constants to the directly bonded phosphorus atoms (ca. 80 Hz ).

Dynamic N.M.R. Spectroscopy.-The observed exchange phenomena in compound (6) can be explained by restricted rotation of the indenyl ligands. The $X$-ray structure reveals that the long axes of all three indenyl groups lie approximately perpendicular to the plane containing $\mathrm{P}(3), \mathrm{P}(4)$, and the three

Figure 1. Molecular structure of compound (5)
rhodium atoms $\operatorname{Rh}(1), \operatorname{Rh}(2)$, and $\operatorname{Rh}(3)$. If all three ligands rotate rapidly about the metal-ligand axes then both sides of this plane will be equivalent. Thus $\mathrm{P}(1)$ and $\mathrm{P}(2)$ would give one signal, as would $C(1)$ and $C(6)$ and also $C(11)$ and $C(16)$. In the indenyl groups themselves, the pairs of atoms on either side of the long axes [e.g. in the case of the indenyl group attached to $R h(1), C(27)$ and $C(28)$ or $C(26)$ and $C(29)]$ are equivalent under the same conditions.

However, if just one of the indenyl rings rotates about the metal-ligand bond slowly on the n.m.r. time-scale this is sufficient to remove the time-averaged symmetry of the molecule about the plane $\mathrm{P}(3)-\mathrm{P}(4)-\mathrm{Rh}(1)-\mathrm{Rh}(2)-\mathrm{Rh}(3)$, so that $\mathrm{P}(1)$ and $P(2)$ and similar pairs of atoms above and below this plane are then no longer symmetrically equivalent. Furthermore, not only are the pairs of atoms either side of the long axis of the indenyl ligand that rotates slowly then inequivalent, all the carbon atoms in both the other indenyl ligands also become different because the molecule is then chiral and these pairs of atoms are diastereotopic. This corresponds exactly to the behaviour observed in the spectra.

Only one indenyl group is strongly hindered. Should two or more indenyl ligands experience restricted rotation then different rotamers would be formed, which would have caused further splitting of all signals.

In order to confirm this interpretation and to attempt to establish which of the indenyl groups experiences the highest barrier to rotation, it was necessary to assign the indenyl signals in more detail. This was achieved by recording a two-dimensional ${ }^{13} \mathrm{C}-{ }^{1} \mathrm{H}$ chemical shift-correlated n.m.r. spectrum using long-range couplings. Since only the carbon nuclei and protons within the same indenyl group couple with one another, the cross-peaks fall in three groups (see Table 7), one from each indenyl ligand.

The ${ }^{13} \mathrm{C}$ chemical shifts of one of the indenyl ligands are very similar to those of complex (4) and they were accordingly assigned to the ligand on $\mathrm{Rh}(3)$. In the other two indenyl groups, the shifts of the ring-junction atoms are 114.0 and 115.0 in one case and 118.4 and 123.1 p.p.m. in the other. Because the ringjunction carbon atoms in the indenyl group attached to $\mathrm{Rh}(1)$ are further away from the metal than those of the other ligand from $\mathrm{Rh}(2)$, the shifts 118.4 and 123.1 p.p.m. were assigned to $\mathrm{C}(21) / \mathrm{C}(25)$ in the indenyl ligand bonded to $\mathrm{Rh}(1)$. Inspection of the data shows that the differences between the chemical

shifts of $C(22) / C(24), C(21) / C(25)$, and $C(26) / C(29)$ are much greater than for the other indenyl groups and therefore we conclude that this must be the ligand for which the rotation is restricted. According to the chemical shifts of $C(21)$ and $C(25)$, this ligand shows the greatest tendency towards $\eta^{3}$ co-ordination (when the indenyl group is $\eta^{3}$ bonded the ring-junction carbon signal is found at ca. 142 p.p.m. ${ }^{9}$ ) and also appears to be in the most crowded environment.

## Conclusion

This study reveals that the reactions of a $\lambda^{3}$-phospha-alkyne with rhodium(I) compounds are more complex than with the corresponding cobalt( $(\mathrm{I})$ compounds. ${ }^{1-3}$ To form the rhodium complex (5) it is necessary to cleave $\mathrm{P} / \mathrm{C}$ bonds of (3). The detection of di(t-butyl)acetylene in the reaction mixture shows that this process does indeed occur, although it is unknown at what stage of the reaction sequence it takes place.
The most interesting feature of complex (6) is the existence of a 1-rhoda-2,5-diphosphacyclopentenediyl unit, which must have been formed by a C -C coupling of two phospha-alkyne molecules. However, in all other dimerization reactions of (3) hitherto known coupling takes place with $\mathrm{P}-\mathrm{C}$ bond formation, in accordance with the charge distribution in the free phosphaalkynes. ${ }^{10}$ One possible explanation for this difference in behaviour is the reaction sequence for the formation of (6) outlined in Scheme 2.
It is assumed that complex (4) is formed initially and then

reacts with a second molecule of (1) by interaction of the metal with the lone pair of one of the phosphorus atoms of the diphosphacyclobutadiene ring. ${ }^{2}$ We postulate that for steric reasons ethylene in adduct (I) can be displaced by (3) only when the latter is 'end-on' co-ordinated. This would also cause a change in the charge distribution in the phospha-alkyne ligand allowing oxidative coupling of this 'end-on' bonded (3) with a free phospha-alkyne to take place with formation of a $\mathrm{C}-\mathrm{C}$ bond. If this is true, the regiochemistry of the oxidative coupling of two phospha-alkynes in the co-ordination sphere of a metal should be influenced by the steric bulk of the other ligands attached to the metal. Experiments to verify this hypothesis are in progress.

## Experimental

All reactions were carried out under oxygen-free argon using Schlenk-tube techniques. Solvents were dried rigorously before use. The n.m.r. spectra were measured with Bruker WP 80 FT $\left({ }^{1} \mathrm{H}, 80 ;{ }^{31} \mathrm{P}, 32.4 \mathrm{MHz}\right.$ ), WM $300 \mathrm{FT}\left({ }^{13} \mathrm{C}, 75.4 ;{ }^{31} \mathrm{P}, 121.4\right.$ MHz ), and AM $200 \mathrm{FT}\left({ }^{1} \mathrm{H}, 200 \mathrm{MHz}\right)$ instruments with $\mathrm{SiMe}_{4}$ as internal standard for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ and $\mathrm{H}_{3} \mathrm{PO}_{4}$ as external standard for ${ }^{31} \mathrm{P}$. The ${ }^{103} \mathrm{Rh}$ n.m.r. spectra ( 12.59 MHz ) were measured by indirect two-dimensional n.m.r. ( 161.9 MHz ) using ${ }^{31} \mathrm{P}$ detection on a Bruker WH-400 instrument. The mass spectra are recorded with a Varian MAT 311 A DF spectrometer at $70 \mathrm{eV}\left(1.12 \times 10^{-17} \mathrm{~J}\right)$. Elemental analyses were performed by the microanalytical laboratory Dornis and Kolbe, Mülheim a. d. Ruhr.
The compounds $\left[\mathrm{Rh}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right](1),{ }^{11}\left[\mathrm{Rh}\left(\eta^{5}-\right.\right.$

$\left.\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\eta^{4}\right.$-cod)] (2), ${ }^{11}$ and $\mathrm{P} \equiv \mathrm{CBu}^{1}(3)^{12}$ were prepared by methods described previously.

Reaction of $\left[\mathrm{Rh}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]$ (1) with $\mathrm{P} \equiv \mathrm{CBu}^{1}(3)$.- A solution of complex ( 1 ) $(1.46 \mathrm{~g}, 5.33 \mathrm{mmol})$ in $\mathrm{Et}_{2} \mathrm{O}\left(50 \mathrm{~cm}^{3}\right)$ was treated with (3) ( $2.42 \mathrm{~g}, 24.20 \mathrm{mmol}$ ). After stirring for $c a .6 \mathrm{~h}$ red crystals of (6) $(0.25 \mathrm{~g}, 13.3 \%)$ precipitated which were isolated by removing the solution by a glass capillary, washing with pentane ( $5 \mathrm{~cm}^{3}$ ), and drying in vacuo. Crystals suitable for $X$-ray analysis were obtained by recrystallization from a mixture of tetrahydrofuran, $\mathrm{Et}_{2} \mathrm{O}$, and pentane in the ratio 1:2:2; m.p. $247^{\circ} \mathrm{C}$ (decomp.). The solvent was removed from the remaining reaction solution in vacuo. In the $-78^{\circ} \mathrm{C}$ condensate di(t-butyl)acetylene was detected by g.c. analysis (identified by comparison of its retention time with that of an authentic sample). The residue was dissolved in toluene ( $400 \mathrm{~cm}^{3}$ ) and chromatographed ( $3 \times 60 \mathrm{~cm}$ column, $\mathrm{Al}_{2} \mathrm{O}_{3}$ ). Elution with this solvent gave a yellow eluate ( $120 \mathrm{~cm}^{3}$ ) and, after an intermediate eluate ( $20 \mathrm{~cm}^{3}$ ), a red eluate ( $150 \mathrm{~cm}^{3}$ ). The solvent was removed from the yellow eluate in vacuo and the residue was dissolved in pentane ( $10 \mathrm{~cm}^{3}$ ), filtered on Celite, and cooled to $-20^{\circ} \mathrm{C}$. Yellow needles of (4) $(0.66 \mathrm{~g}, 30 \%)$ were obtained which were isolated by filtration and drying in vacuo; m.p. $119{ }^{\circ} \mathrm{C}$. Complex (5) was obtained in the same manner as red crystals from the red eluate ( $50 \mathrm{mg}, 2.6 \%$ ) after removing toluene, dissolving in $\mathrm{Et}_{2} \mathrm{O}\left(10 \mathrm{~cm}^{3}\right)$, and cooling to $-78^{\circ} \mathrm{C}$; m.p. $148{ }^{\circ} \mathrm{C}$ (decomp.).

Complex (4). $m / z=418$ ( $62, M^{+}$for ${ }^{103} \mathrm{Rh}$ ), 280 ( 100 , $\left.\left[\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{P}_{2} \mathrm{Rh}\right]^{+}\right), 218\left(59,\left[\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{Rh}\right]^{+}\right)$, and $115\left(17 \%,\left[\mathrm{C}_{9} \mathrm{H}_{7}\right]^{+}\right)$ (Found: C, 54.35; H, 6.50; Rh, 24.40. Calc. for $\mathrm{C}_{19} \mathrm{H}_{25} \mathrm{P}_{2} \mathrm{Rh}$ : C, $54.55 ; \mathrm{H}, 6.00 ; \mathrm{Rh}, 24.60 \%$ ). powder ( $0.52 \mathrm{~g}, 36 \%$ ) after evaporation of the solvent to half volume, cooling to $-78^{\circ} \mathrm{C}$, and filtration.

Crystal Structure Determinations.-Both data sets were collected on an Enraf-Nonius CAD 4 diffractometer with graphite-

Scheme 2. (i) $\mathrm{P}=\mathrm{CBu}^{\prime}$; (ii) complex (1)
monochromated Mo- $K_{\alpha} X$-radiation ( $\lambda=0.71069 \AA$ ) by a $\theta$ $2 \theta$ scan technique. The intensities of three standard reflections, remeasured every 100 reflections, showed no significant variation during data collection. The data sets were corrected for Lorentz and polarization effects and data for complex (5) were also corrected for absorption; $\sigma(F)$ was calculated from $\left[\sigma(I)^{2}+(I k)\right]^{2} / 2 F$, where $k=0.02$. Equivalent reflections were averaged. Only intensities that satisfied the criterion $I>$ $2.0 \sigma(I)$ were used in the solution and refinement of the structure.

The structures were solved by the heavy-atom method. Refinement was by full-matrix least-squares methods, where the function minimized was $\Sigma w(\Delta F)^{2}$ with $w=1 / \sigma(F)^{2}$ and $\Delta F=$ $\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|$. The H atoms of (5) were located in a difference Fourier synthesis and included isotropically in the refinement with fixed isotropic thermal parameters; those of (6) were inserted at calculated positions with fixed isotropic thermal parameters ( $0.08 \AA^{2}$ ) and not refined. Atomic scattering curves were taken from ref. 13.

Crystal data for complex (5). $\mathrm{C}_{28} \mathrm{H}_{32} \mathrm{P}_{4} \mathrm{Rh}_{2}, M=698.3$, dark red, crystal dimensions $0.29 \times 0.36 \times 0.22 \mathrm{~mm}$, monoclinic, space group $P 2_{1} / c, a=11.890(2), b=19.631(3), c=$ $12.535(1) \AA, \beta=105.51(1)^{\circ}, U=2819.3 \AA^{3}, Z=4, D_{c}=$ $1.64 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=13.92 \mathrm{~cm}^{-1}, F(000)=1400$.

6845 Reflections were collected in the range $1.04<\theta<$ 27.33. Empirical absorption correction: minimum 0.824 , maximum 1.174. 5338 Observed reflections, $R=0.026, R^{\prime}=0.031$.

Crystal data for complex (6). $\mathrm{C}_{47} \mathrm{H}_{57} \mathrm{P}_{4} \mathrm{Rh}_{3}, M=1054.6$, dark red, crystal dimensions $0.07 \times 0.50 \times 0.14 \mathrm{~mm}$, triclinic,
