Kinetics of Oxidation of Aromatic Hydrocarbons and Tetrahydrofuran by *trans*-Dioxoruthenium(vi) Complexes

Chi-Ming Che,* Wai-Tong Tang, Kwok-Yin Wong and Chi-Keung Li
Department of Chemistry, University of Hong Kong, Pokfulam Road, Hong Kong

The kinetics of oxidation of aromatic hydrocarbons and tetrahydrofuran by trans-[Ru^{vi}LO₂]²⁺ {L = 2 bipy(bipy = 2,2'-bipyridine), L¹ = 6,7,14,15,16,17,18,19-octahydro-14,18-dimethyl-13*H*-dibenzo[*e,n*]-[1,4,8,12]dioxadiazacyclopentadecine, L² = N,N'-dimethyl-N,N'-bis(2-pyridylmethyl)propylenediamine and L³ = meso-2,3,7,11,12-pentamethyl-3,7,11,17-tetraazabicyclo[11.3.1]heptadeca-1(17),13,15-triene} has been studied. In acetonitrile the second-order rate constants follow the order: toluene < ethylbenzene < cumene. The kinetic isotope effects for the oxidation of ethylbenzene by trans-[RuLO₂]²⁺ (L = L¹ or L²) are 16 and 12:1 respectively. In the oxidation of tetrahydrofuran by trans-[RuL¹O₂]²⁺, t_2 was found to be 0.170 mol⁻¹ dm³ s⁻¹ at 298 K with a measured kinetic isotope effect of 20:1. A linear correlation between log(rate constant) and t_2 (Ru^{vi}-Ru^{iv}) for the oxidation of tetrahydrofuran has been observed. The activation parameters for the oxidation reactions have also been determined. A hydrogen-atom abstraction mechanism is suggested for the oxidation of C-H bonds by trans-dioxoruthenium(vi) complexes.

The selective functionalization of C-H bonds under mild conditions is an important area of research.¹ Recent work by various groups has shown that oxoruthenium complexes are capable of oxidizing a wide variety of organic substrates.² Mechanistic studies on the oxidation of hydrocarbons by some oxoruthenium-(IV)³ and -(V)⁴ systems suggested a hydrogenatom or hydride-transfer mechanism. Herein are described kinetic studies on the oxidation of C-H bonds in aromatic hydrocarbons and tetrahydrofuran by some *trans*-dioxoruthenium(VI) complexes.

Experimental

Materials.—Deionized water used in kinetic studies was doubly distilled over alkaline KMnO₄. Trifluoroacetic acid (Aldrich) was purified by distillation under nitrogen. Acetonitrile (Mallinkrodt AR) was first treated with KMnO₄ overnight and then distilled over CaH₂ under nitrogen. [2H₁₀]Ethylbenzene and [2H8]tetrahydrofuran (Aldrich) were used as received. Tetrabutylammonium tetrafluoroborate (Electrometric grade, Southwestern Chemical) was vacuum dried overnight at 65 °C. The organic substrates were of analytical grade and purified by repeated recrystallization or fractional distillation. The compounds trans-[Ru^{VI}L¹O₂][ClO₄]₂ (L¹ = 6,7,14,15,16,17, 18,19-octahydro-14,18-dimethyl-13H-dibenzo[e,n][1,4,8,12]dioxadiazacyclopentadecine), trans-[RuVIL²O₂][ClO₄]₂ [L² = N,N'-dimethyl-N,N'-bis(2-pyridylmethyl)propylenediamine],⁶ trans-[Ru^{VI}(bipy)₂O₂][ClO₄]₂ (bipy = 2,2'-bipyridine)' and trans-[Ru^{VI}L³O₂][ClO₄]₂ {L³ = meso-2,3,7,11,12- pentamethyl-3,7,11,17-tetraazabicyclo[11.3.1]heptadeca-1(17),13,15triene} 8 were prepared as described previously.

Instrumentation and Techniques.—Kinetic experiments employed either a Unicam SP8000 spectrophotometer linked to an Apple IIe microcomputer or a HI-TECH SF-51 stopped-flow spectrophotometer. Temperature was maintained to $\pm 0.1~^{\circ}$ C with a thermostatted water-bath. The rate of reaction was followed by monitoring the decrease in absorbance of the ruthenium complex at 350–400 nm. Pseudo-first-order rate constants were calculated on the basis of a least-squares fit by the relation $\ln|A_{\infty} - A_{\rm c}| = -k_{\rm obs}t + \ln|A_{\infty} - A_{\rm o}|$ where A_{∞} is the final absorbance upon completion of reaction, $A_{\rm o}$ the initial

absorbance and A_t the absorbance at time t and $k_{\rm obs}$ is the first-order rate constant. Runs were initiated by mixing equal volumes of a 1 mmol dm⁻³ solution of the ruthenium complex and a known concentration of organic substrate in at least tenfold excess. Each run was repeated three times and the mean value of $k_{\rm obs}$ taken. Kinetic data over five half-lives were used for the calculation of $k_{\rm obs}$. The second-order rate constants (k_2) were obtained from plots of $k_{\rm obs}$ vs. [organic substrate]. Activation parameters ΔH^{\ddagger} and ΔS^{\ddagger} were obtained from the slope and intercept of plots of $\ln(k_2/T)$ vs. 1/T.

Results and Discussion

Oxidation of Aromatic Hydrocarbons.—The stoichiometric oxidation of toluene, ethylbenzene and cumene by trans- $[Ru^{VI}LO_2]^{2+}$ (L = L¹ or L²) has been studied and reported.^{5,6} Toluene was oxidized to benzaldehyde. With ethylbenzene, the secondary C-H bond was oxidized to give acetophenone and sec-phenylethyl alcohol. In the case of cumene only 2-phenyl isopropyl alcohol was obtained. Thus, trans- $[Ru^{VI}LO_2]^{2+}$ selectively oxidise tertiary C-H bonds in the presence of primary and secondary ones.

Spectral changes with clean isosbestic points (Fig. 1) were

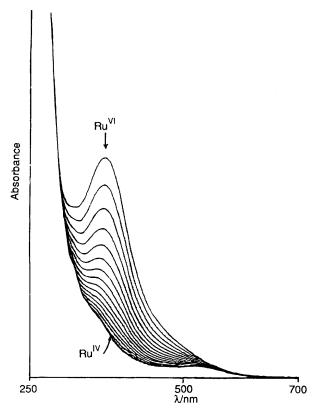

Fig. 1 UV/VIS spectral changes for the reaction between *trans*-[RuL $^{1}O_{2}$] $^{2+}$ (10^{-3} mol dm $^{-3}$) and cumene (1 mol dm $^{-3}$) at room temperature in acetonitrile. Scan interval 2 min

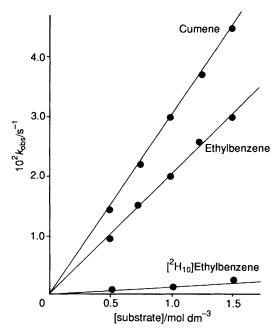

Fig. 2 Plots of $k_{\rm obs}$ vs. [aromatic hydrocarbon] for the oxidation of aromatic hydrocarbons by trans-[RuL¹O₂]²⁺ in acetonitrile at 298 K

obtained for the oxidation of the above aromatic hydrocarbons by trans- $[RuL^1O_2]^{2+}$. The UV/VIS spectrum of the final ruthenium product is identical to that of trans- $[Ru^{IV}L^1(O)-(OH_2)]^{2+}$ in acetonitrile ⁵ indicating that the reaction involved the reduction of Ru^{VI} to Ru^{IV} .

Under the condition that [aromatic hydrocarbon] \gg [Ru^{VI}], the experimental rate law was found to be as in equation (1)

$$rate = k_{obs}[Ru^{VI}]$$
 (1)

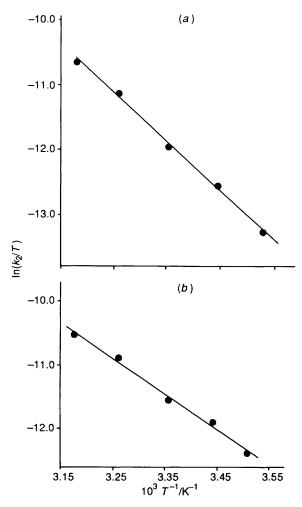

Fig. 3 Eyring plots for the oxidation of (a) ethylbenzene and (b) cumene by trans-[RuL¹O₂]²⁺ in acetonitrile

where $k_{\rm obs} = k_2$ [aromatic hydrocarbon]. Fig. 2 shows plots of $k_{\rm obs}$ vs. [aromatic hydrocarbon] for the oxidation by trans-[RuL¹O₂]²+. The rate constants k_2 (Table 1) follow the order toluene < ethylbenzene < cumene. The fact that toluene was oxidized to benzaldehyde suggests a two-step reaction [equations (2) and (3)].

$$Ru^{VI} + PhCH_3 \longrightarrow Ru^{IV} + PhCH_2OH$$
 (2)

$$Ru^{VI} + PhCH_2OH \longrightarrow Ru^{IV} + PhCHO$$
 (3)

At 298 K, k_2 for the oxidation of benzyl alcohol and toluene by trans-[RuL¹O₂]²⁺ is 0.54 and 1.8×10^{-5} dm³ mol⁻¹ s⁻¹ respectively. This suggests that benzyl alcohol is 10^4 times more reactive than toluene. In order to avoid the secondary reduction of Ru^{VI} by benzyl alcohol, a large excess (× 1000) of toluene was used in the kinetic studies. In the stoichiometric oxidation of ethylbenzene, acetophenone was formed. It is likely that this came from the oxidation of sec-phenylethyl alcohol by trans-[Ru^{VI}LO₂]²⁺. In order to determine the extent of α -C-H bond cleavage in the activation step, the oxidation of [²H₁₀]ethylbenzene by trans-[Ru^{VI}LO₂]²⁺ has also been studied. The measured $k_{\rm H}/k_{\rm D}$ of 16 ± 2 and 12 ± 2 :1 (Table 1) for L = L¹ and L² respectively strongly suggests an important role for such bond cleavage.

Activation parameters for the oxidation of cumene and ethylbenzene were determined over the temperature range 283–315 K and the results are summarized in Table 1. Two representative Eyring plots are given in Fig. 3. The negative ΔS^{\ddagger} values and large kinetic isotope effect on the rate constants

indicate a transition state having strong lead-in interaction between the α -C-H bond of the aromatic hydrocarbons and the Ru=O moiety of trans-[Ru^{VI}LO₂]²⁺.

Either a hydrogen-atom or hydride-abstraction mechanism is possible. There is no evidence for the formation of products arising from coupling of PhC(CH₃)₂ radicals in the oxidation of cumene. This, together with the fact that the yields of organic products and rate constants for oxidation are independent of the addition of radical scavengers, strongly argues against a mechanism involving the formation of out-cage radical intermediates. Scheme 1 outlines a possible mechanism for the oxidation. Pathway a involves an initial hydrogen-atom abstraction followed by a rapid in-cage one-electron transfer before the radical intermediates R* and O=Ru*OH diffuse out to the solution. Such a pathway would be very difficult to distinguish from pathway b which involves a two-electron hydride abstraction. Pathway c involves a concerted transition state.

Thompson and Meyer ^{3a} have shown that both solvent and added nucleophile play an important role in the oxidation of aromatic hydrocarbons by [Ru(bipy)₂(py)O]²⁺ (py = pyridine). Presumably, the added nucleophile assists the loss of hydride ion by charge neutralization at the metal atom with

electron-pair donation as hydride transfer occurs to Ru=O. In this work, however, water or Bu'OH was found to have no effect on the rate of oxidation of cumene by *trans*-[RuL¹O₂]²⁺ (Table 1).

From Table 1, there is only a small difference in the rates of oxidation of cumene and ethylbenzene in contrast to the difference in the secondary and tertiary C-H bond energy. This may be attributed to the presence of methyl groups in cumene that hinder the approach of the ruthenium oxidant.

Oxidation of Tetrahydrofuran.—In stoichiometric oxidation, tetrahydrofuran (thf) was oxidized by trans-dioxoruthenium(v1) to γ -butyrolactone. The kinetics of oxidation by trans-[Ru^{VI}LO₂]²⁺ was studied in 0.1 mol dm⁻³ CF₃CO₂H. For L = L¹ well defined isosbestic points at 295 and 650 nm were observed throughout the reaction, the spectral changes being the same as those shown in Fig. 1. The UV/VIS spectrum of the final product is identical to that of Ru^{IV}. Thus the reaction can be described as a two step process [equations (4) and (5)].

The experimental rate law found is as in equation (6) where

$$rate = k_{obs}[Ru^{VI}]$$
 (6)

 $k_{\rm obs}=k_2$ [thf]. The kinetic data are summarized in Table 1. Fig. 4 shows a representative plot of $k_{\rm obs}$ versus [thf]. For the oxidation by trans- $[Ru^{\rm VI}L^1O_2]^{2^+}$ the kinetic isotope effect $k_{\rm H}/k_{\rm D}$ was found to be $20\pm2:1$, substantially larger than that reported by Lee and Engl ¹⁰ for the oxidation of tetrahydrofuran by RuO_4 ($k_{\rm H}/k_{\rm D}=1.5:1$). The activation parameters for the oxidation by trans- $[Ru^{\rm VI}LO_2]^{2^+}$ ($L=L^1$ or L^3) are summarized in Table 1. Fig. 5 shows a plot of log k_2 versus E° ($Ru^{\rm VI}-Ru^{\rm IV}$) for trans- $[Ru^{\rm VI}LO_2]^{2^+}$. The best straight line drawn has a slope of 19.6 V⁻¹.

General.—Previous electrochemical studies revealed that trans- $[Ru^{VI}LO_2]^{2+}$ functions either as a two- or a one-electron

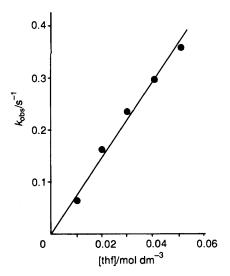

Fig. 4 Plot of k_{obs} vs. [tetrahydrofuran] for the oxidation by trans-[Ru(bipy)₂O₂]²⁺ in 0.1 mol dm⁻³ CF₃CO₂H at 298 K

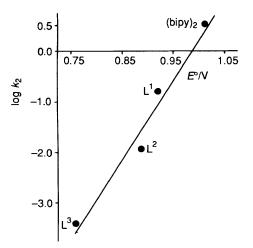

Fig. 5 Plot of $\log k_2$ vs. E° of the Ru^{VI} - Ru^{IV} couple for the oxidation of tetrahydrofuran by trans- $[Ru^{VI}LO_2]^{2+}$ in 0.1 mol dm⁻³ CF₃CO₂H at 298 K

oxidant, depending on the pH of the medium. At pH 1 the E° (Ru^{VI}–Ru^{IV}) values are 1.01, 0.92, 0.89 and 0.76 V vs. saturated calomel electrode for L = (bipy)₂, L¹, L² and L³ respectively, ⁵⁻⁸ suggesting that these oxoruthenium(VI) complexes are strong oxidants.

In this work the kinetic isotope effects $(k_{\rm H}/k_{\rm D})$ for the oxidation of ethylbenzene and tetrahydrofuran by trans- $[{\rm RuL^1O_2}]^{2+}$ are 16 ± 2 and $20\pm 2:1$ respectively, comparable to those of $14\pm 2:1$ for the oxidation of cyclohexane by trans- $[{\rm Ru}(5,5'\text{-dmbipy})_2{\rm O_2}]^{2+}$ (5,5'-dmbipy = 5,5'-dimethyl-2,2'-bipyridine)¹¹ and $12\pm 2:1$ for the oxidation of ethylbenzene by trans- $[{\rm RuL^2O_2}]^{2+}$. This suggests a common linear $[{\rm O=Ru^{VI}=O \cdot \cdot \cdot H-C-1}]$ transition state. Such an associative

mechanism is also supported by the large negative ΔS^{t} values for the oxidation reactions. Several pathways are feasible for the oxidation of C-H bonds by trans-[Ru^{VI}LO₂]²⁺ (Scheme 1).

Pathways a and b are the two-electron hydride and one-electron hydrogen-atom abstraction respectively. It is difficult to distinguish between them, especially in the case where the hydrogen-atom abstraction is followed by a rapid in-cage oxygen rebound or electron transfer from O=Ru^V-OH to the R* radical. However, in view of previous results on the oxidation of cyclohexane by trans-[Ru^{VI}(5,5-dmbipy)₂O₂]²⁺,¹¹ a H-atom abstraction is favoured for the oxidation of aromatic hydrocarbons by trans-dioxoruthenium(VI). Pathway c is a concerted insertion process but in view of the large kinetic isotope effects for the oxidation we favour a linear transition state.

The C-H bond oxidation by trans-[RuVILO₂]²⁺ is likely to be facilitated by charge transfer from the C-H bond to the RuVI=O oxidant. This is at least true for tetrahydrofuran where a linear free-energy relationship between the rate constants and E° of trans-[RuVILO₂]²⁺ has been observed (Fig. 5). For the oxidation of cumene and ethylbenzene, trans-[RuL¹O₂]²⁺ has higher rate constants than those of trans-[RuL²O₂]²⁺ because the former oxidant has a higher E° . trans-Dioxo(1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane)ruthenium(VI) with a E° value ≈ 200 mV lower than that of trans-[RuL²O₂]²⁺ has been reported to be inactive towards oxidation of aromatic hydrocarbons at room temperature.¹²
