Treatment of $\mathrm{U}\left(\mathrm{NEt}_{2}\right)_{4}$ with PhSH gave $\left[\mathrm{NEt}_{2} \mathrm{H}_{2}\right]_{2}\left[\mathrm{U}(\mathrm{SPh})_{6}\right]$ 1. Reaction of $\mathrm{UCl}_{4}$ with NaSPh in the presence of CuSPh and $\mathrm{PPh}_{3}$ afforded $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3} \mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right]$ 2. The geometrical parameters of the octahedral $U S_{6}$ core are quite similar in the crystal structures of 1, 2.6thf and $\left[(\text { thf })_{3} \mathrm{Na}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3} \mathrm{Na}(\text { thf })_{3}\right]$ (thf = tetrahydrofuran). The $\mathrm{U}-\mathrm{Cu}$ distance of $3.05(1) \AA$ supports the presence of a direct metal-metal interaction.

We recently described the synthesis and crystal structure of the uranium compounds $\left[(\mathrm{thf})_{3} \mathrm{Na}(\mu-\mathrm{SR})_{3} \mathrm{U}(\mu-\mathrm{SR})_{3} \mathrm{Na}(\text { thf })_{3}\right]$ (thf $=$ tetrahydrofuran, $\mathrm{R}=\mathrm{Bu}^{t}$ or Ph$)^{1}$ which represent, after $\mathrm{U}(\mathrm{SR})_{4}\left(\mathrm{R}=\mathrm{Et}, \mathrm{Bu}^{n}\right.$ or $\left.\mathrm{Pr}{ }^{\mathrm{i}}\right),{ }^{2,3}\left[\mathrm{Li}\left(\mathrm{MeOCH}_{2} \mathrm{CH}_{2} \mathrm{O}-\right.\right.$ $\mathrm{Me})]_{4}\left[\mathrm{U}\left(\mathrm{SCH}_{2} \mathrm{CH}_{2} \mathrm{~S}\right)_{4}\right]^{4}$ and $\left[\mathrm{Li}\left(\mathrm{Me}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NMe}_{2}\right)\right]_{3}-$ $\left[\mathrm{M}\left(\mathrm{SBu}^{1}\right)_{6}\right](\mathrm{M}=\mathrm{Yb}$ or Sm$),{ }^{5}$ new examples of homoleptic thiolates of an $f$ element. Six-co-ordinate, homoleptic, transi-tion-metal complexes with monodentate thiolate ligands are rare, being limited to $\left[\mathrm{PPh}_{4}\right]_{2}\left[\mathrm{Nb}(\mathrm{SPh})_{6}\right]$, $[\text { (thf })_{3} \mathrm{Na}\left(\mu-\mathrm{SC}_{6}-\right.$ $\left.\left.\mathrm{H}_{4} \mathrm{Me}-p\right)_{3} \mathrm{Nb}\left(\mathrm{SC}_{6} \mathrm{H}_{4} \mathrm{Me}-p\right)_{3}\right], \quad\left[\mathrm{Na}\left(\mathrm{C}_{10} \mathrm{H}_{20} \mathrm{O}_{5}\right)\right]\left[\mathrm{Ta}(\mathrm{SPh})_{6}\right]^{6}$ and $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}\left(\mu-\mathrm{SC}_{6} \mathrm{H}_{4} \mathrm{Me}-p\right)_{3} \mathrm{M}\left(\mu-\mathrm{SC}_{6} \mathrm{H}_{4} \mathrm{Me}-p\right)_{3} \mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right]$ ( $\mathrm{M}=\mathrm{Mo}$ or W ). ${ }^{7}$ In order to obtain a better insight into the geometry of the $\mathrm{U}(\mathrm{SPh})_{6}$ entity and to make valid comparisons with the other transition-metal analogues, we have studied the complexes $\left[\mathrm{NEt}_{2} \mathrm{H}_{2}\right]_{2}\left[\mathrm{U}(\mathrm{SPh})_{6}\right] 1$ and $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3} \mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right]$ 2. Therefore we present herein the synthesis and crystal structure of 1 and of a thf solvate of 2.

## Results and Discussion

Synthesis.-In contrast to the previously reported reactions of $\mathrm{U}\left(\mathrm{NEt}_{2}\right)_{4}$ with thiols which afforded the tetrathiolates $\mathrm{U}(\mathrm{SR})_{4}\left(\mathrm{R}=\mathrm{Et}, \mathrm{Bu}^{\mathrm{n}} \text { or } \mathrm{Pr}^{\mathrm{i}}\right)^{2,3}$ or the cluster $\left[\mathrm{U}_{3}(\mathrm{~S})\left(\mathrm{SBu}^{\mathrm{t}}\right)_{10}\right],{ }^{3}$ treatment of the uranium amide complex with an excess of PhSH in thf immediately gave a red solution which deposited, upon cooling, light red crystals of $\left[\mathrm{NEt}_{2} \mathrm{H}_{2}\right]_{2}\left[\mathrm{U}(\mathrm{SPh})_{6}\right] \mathbf{1}(73 \%$ yield). This distinct reaction course is obviously due to the greater acidity of the thiophenol, which is deprotonated by the liberated amine $\mathrm{NEt}_{2} \mathrm{H}$. Complex 1 was characterized by elemental analyses and X-ray crystallography (see later).
The trinuclear compound $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3}-\right.$ $\left.\mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right]$ 2, which is the first heterobimetallic complex containing a 5 f element and a copper atom in close proximity, was prepared in thf by mixing $\mathrm{UCl}_{4}, \mathrm{NaSPh}, \mathrm{CuSPh}$ and $\mathrm{PPh}_{3}$ in the relative molar proportions $1: 4: 2: 2$. A red powder precipitated immediately and after filtration, extraction in thf and crystallization from this solvent, dark red crystals of 2.6 thf were isolated in $60 \%$ yield. These crystals were suitable for an

[^0]

Fig. 1 Perspective view of $\left[\mathrm{NEt}_{2} \mathrm{H}_{2}\right]_{2}\left[\mathrm{U}(\mathrm{SPh})_{6}\right]$; atoms labelled i are related by a centre of symmetry

X-ray diffraction analysis (see later); by drying under vacuum, they were transformed into a powder of unsolvated 2 , which gave satisfactory elemental analyses. The ${ }^{1} \mathrm{H}$ NMR spectrum exhibited two similar sets of three signals, in a $2: 2: 1$ ratio, corresponding to the $\mathrm{C}_{6} \mathrm{H}_{5}$ groups of the triphenylphosphine and benzenethiolate ligands. These two series of resonances were visible in the opposite regions of the spectrum, in agreement with the theoretical expression for the pseudocontact shifts in axial symmetry, ${ }^{8}$ and by analogy with the spectra of the complexes $\left[(\text { thf })_{3} \mathrm{Na}(\mu-\mathrm{SR})_{3} \mathrm{U}(\mu-\mathrm{SR})_{3} \mathrm{Na}-\right.$ (thf) $)_{3},{ }^{1}$ the low-field signals would be attributed to the SPh ligands.

Crystal Structures.-The crystals of compound 1 are composed of discrete cation-anion pairs. The ORTEP drawing ${ }^{9}$ of the $\left[\mathrm{U}(\mathrm{SPh})_{6}\right]^{2-}$ dianion is shown in Fig. 1; selected bond distances and angles are listed in Table 1. The uranium atom, which lies on an inversion centre, is surrounded by six sulfur atoms in a slightly distorted octahedral environment. The U-S
bond distances vary from $2.705(3)$ to $2.759(3) \AA$ and the cis S-U-S angles range from 81.2(1) to 83.0 (1).

Following the proposal of Stiefel and Brown, ${ }^{10}$ the six-coordinate polyhedron of $D_{3}$ symmetry can be defined by the two parameters $\Phi$ and $s / h$, i.e. the twist angle between two triangular faces of the polyhedron and the ratio of the side of the triangle to the distance between the triangles (see below).

In $\mathbf{1}, \Phi$ is equal to $60^{\circ}$, as in the undistorted octahedron, but $s / h$ is equal to $1.01[s=3.58(2) \AA$ and $h=3.55(2) \AA]$ instead of 1.22 in the regular octahedron, indicating that the structure is elongated along one of the pseudo $C_{3}$ axes. This trigonal elongation can also be measured either by the cis S-U-S angles which deviate by $8^{\circ}$ from the ideal value in the octahedron $\left(90^{\circ}\right)$ or the polar angle $\theta$ between the $C_{3}$ axis and the U-S direction, which is equal to $49.5^{\circ}$ instead of $54.44^{\circ}$ for the perfect octahedron. The geometry of the $\mathrm{US}_{6}$ core in $\mathbf{1}$ is very similar to
that found in the centrosymmetric anions $\left[\mathrm{Nb}(\mathrm{SPh})_{6}\right]^{2-}$ and $\left[\mathrm{Ta}(\mathrm{SPh})_{6}\right]^{-}$where the cis S-M-S angles average 87 and $85^{\circ}$ respectively. ${ }^{6}$ The octahedral co-ordination of these homoleptic complexes with monodentate thiolate ligands differs markedly from that encountered in the series of tris(dithiolene) or tris(dithiolate) compounds which prefer to adopt a trigonalprismatic stereochemistry ( $\Phi=0$ and $s / h=1$ in many cases). ${ }^{11}$ These distortions away from the octahedron toward the trigonal prism, which are more important than would be expected from simple repulsion-energy calculations, ${ }^{12}$ have been explained by interligand bonding interactions within the $\mathrm{S}_{3}$ triangles and by optimum overlap between the sulfur $\pi$ orbitals and the metal d orbitals. ${ }^{13}$ It is noteworthy that the geometrical parameters of the $\mathrm{U}(\mathrm{SPh})_{6}$ fragment are quite identical in 1 and in the trinuclear complex [(thf) $)_{3} \mathrm{Na}(\mu-$ $\left.\mathrm{SR})_{3} \mathrm{U}(\mu-\mathrm{SR})_{3} \mathrm{Na}(\text { thf })_{3}\right]$ (Table 2), ${ }^{1}$ showing that in the latter the elongation along the $C_{3}$ axis cannot be attributed to the presence of the capping sodium atom. In contrast, the structure of the $\mathrm{M}(\mathrm{SR})_{6}$ unit, which is octahedral in $\left[\mathrm{PPh}_{4}\right]_{2}-$ $\left[\mathrm{Nb}(\mathrm{SPh})_{6}\right]$ and $\left[\mathrm{Na}\left(\mathrm{C}_{10} \mathrm{H}_{20} \mathrm{O}_{5}\right)\right]\left[\mathrm{Ta}(\mathrm{SPh})_{6}\right]$, is nearly tri-gonal-prismatic in $\left[(\text { thf })_{3} \mathrm{Na}\left(\mu-\mathrm{SC}_{6} \mathrm{H}_{4} \mathrm{Me}-p\right)_{3} \mathrm{Nb}\left(\mathrm{SC}_{6} \mathrm{H}_{4}-\right.\right.$ $\left.\mathrm{Me}-p)_{3}\right] .{ }^{6}$

The geometry of the tetrahedral cation $\left[\mathrm{NEt}_{2} \mathrm{H}_{2}\right]^{+}$is unexceptional, with the $\mathrm{C}-\mathrm{N}-\mathrm{C}$ angle and the $\mathrm{N}-\mathrm{C}$ distance $111.7(9)^{\circ}$ and $1.50(2) \AA$ respectively.

The crystal structure of $\mathbf{2} \cdot 6$ thf revealed that the unit cell

contains three molecules of $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3}-\right.$ $\left.\mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right]$ (Fig. 2); two of these are different from the other since the uranium atoms occupy two independent positions. Both distinct molecules possess a three-fold axis of symmetry passing through the uranium, the two copper and the two phosphorus atoms, but one has also its uranium [U(1)] on an inversion centre. The two independent molecules can be regarded as rotational conformers about the ternary axis and they differ essentially by the relative orientations of the four parallel equilateral triangles defined by the bridging sulfur atoms and the ipso carbons of the $\mathrm{PPh}_{3}$ ligands. The second molecule, which is shown in Fig. 3, adopts a conformation in which two adjacent triangles are in almost perfectly staggered positions; this conformation would be the best for minimization of the interactions between the thiolate and phosphine ligands. The main deviation from the idealized geometry comes from the

Fig. 2 View of the unit cell of $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3} \mathrm{Cu}\right.$ $\left.\left(\mathrm{PPh}_{3}\right)\right]$.6thf along the ternary axis
sulfur triangle containing $S(2)$ which is rotated by about $8^{\circ}$ from the adequate position ( $\Phi=52^{\circ}$ ). In the other molecule which has an inversion centre, the sulfur triangles, which are perfectly staggered ( $\Phi=60^{\circ}$ ) because of the imposed symmetry, and the carbon triangles are rotated about $15^{\circ}$ from eclipsed (or perfectly staggered) orientations. These conformational differences between the two molecules of 2 cannot be easily interpreted, although lattice packing forces could always be invoked. In its two forms, the structure of $\mathbf{2}$ is built up of an uranium-centred octahedron sharing parallel faces with two copper-centred tetrahedra. The geometry of the $\mathrm{Cu}\left(\mathrm{PPh}_{3}\right)$ fragment is unexceptional and the hexathiolatouranium(IV) core is very similar to that encountered in 1 and in $\left[(\text { thf })_{3} \mathrm{Na}(\mu-\right.$ $\mathrm{SR})_{3} \mathrm{U}(\mu-\mathrm{SR})_{3} \mathrm{Na}(\text { thf })_{3}$ ] (Table 1). The twisting distortion in one molecule has already been mentioned; the other small difference visible in the two conformers of $\mathbf{2}$ is the slightly more

pronounced trigonal elongation of the $\mathrm{US}_{6}$ octahedron, as indicated by the parameters listed in Table 2.
The structure of complex 2 bears a strong resemblance to that of the molybdenum and tungsten analogues $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\right.$ $\left.\left.\mathrm{SC}_{6} \mathrm{H}_{4} \mathrm{Me}-p\right)_{3} \mathrm{M}\left(\mu-\mathrm{SC}_{6} \mathrm{H}_{4} \mathrm{Me}-p\right)_{3} \mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right](\mathrm{M}=\mathrm{Mo}$ or W$)$, recently isolated by Boorman and co-workers. ${ }^{7}$ In these centrosymmetric molecules, the $\mathrm{MS}_{6}$ core is quite perfectly octahedral $\left[\Phi=60^{\circ}\right.$, S-Mo-S $\left.88.6(1)^{\circ}, \theta=53.7(1)^{\circ}\right]$. The $\mathrm{M}-\mathrm{S}-\mathrm{Cu}$ angles and $\mathrm{M}-\mathrm{Cu}$ distances led the authors to consider that there was some degree of bonding interaction between the Cu and the Mo or W atoms. Such dative bonds between an early, Lewis acidic and late, electron-rich metal centres have in fact been inferred in a great number of thiolatobridged heterobimetallics, from the angles at the bridging sulfur atoms and the metal-metal distances. ${ }^{14}$ In the trinuclear complex 2, the U-S-Cu angles which are less than $80^{\circ}$ and the $\mathrm{U}-\mathrm{Cu}$ bond length which is close to the sum of the atomic radii of these metals ( $3.1 \AA$ ), ${ }^{15}$ also support the presence of a direct $\mathrm{U}-\mathrm{Cu}$ interaction. The $\mathrm{U}-\mathrm{Cu}$ distances in the alloy $\mathrm{UCu}_{5}$ were found to be equal to 2.92 and $3.05 \AA \AA^{16}$ Similarly closed actinide-transition-metal contacts have been observed in the phosphido-bridged compounds $\left[\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right)_{2} \mathrm{Th}\left(\mu-\mathrm{PPh}_{2}\right)_{2} \mathrm{Ni}\right.$ -$\left.(\mathrm{CO})_{2}\right][\mathrm{Th}-\mathrm{Ni} 3.206(2) \AA]^{17}$ and $\left[\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right)_{2} \mathrm{Th}\left(\mu-\mathrm{PPh}_{2}\right)_{2}-\right.$ $\left.\mathrm{Pt}\left(\mathrm{PMe}_{3}\right)\right][\mathrm{Th}-\mathrm{Pt} 2.984(1) \AA] .{ }^{18}$

## Experimental

All preparations and reactions were carried out under argon ( $<5 \mathrm{ppm}$ oxygen or water) using standard Schlenk-vessel and vacuum-line techniques or in a glove-box. Solvents were thoroughly dried and deoxygenated by standard methods and distilled immediately before use; $\left[{ }^{2} \mathrm{H}_{8}\right]$ thf was dried over $\mathrm{Na}-\mathrm{K}$ alloy.
Elemental analyses were performed by Analytische Laboratorien at Engelskirchen (Germany). The ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a Bruker WP $60(\mathrm{FT})$ instrument and were referenced internally using the residual protio solvent resonances relative to tetramethylsilane ( $\delta 0$ ). Benzenethiol (Aldrich) was dried over molecular sieves; NaSPh was obtained as a white powder after the reaction of sodium and a slight excess of PhSH (1.1 equivalent) in thf. The compounds CuSPh (Fluka) and $\mathrm{PPh}_{3}$ (Aldrich) were dried under vacuum. Both $\mathrm{UCl}_{4}{ }^{19}$ and $\mathrm{U}\left(\mathrm{NEt}_{2}\right)_{4}{ }^{20}$ were prepared by published methods.
$\left[\mathrm{NEtH}_{2}\right]_{2}\left[\mathrm{U}(\mathrm{SPh})_{6}\right]$ 1.-A round bottomed flask $\left(100 \mathrm{~cm}^{3}\right)$ was charged with $\mathrm{U}\left(\mathrm{NEt}_{2}\right)_{4}(900 \mathrm{mg}, 1.7 \mathrm{mmol})$ in thf $\left(50 \mathrm{~cm}^{3}\right)$ and PhSH ( $1900 \mathrm{mg}, 17.3 \mathrm{mmol}$ ) was added to the green solution which turned red immediately. After stirring for 15 $\min$, the solvent was evaporated and the residue dried under vacuum for 1 h . The solid was dissolved in thf $\left(30 \mathrm{~cm}^{3}\right)$ and the solution was filtered. Upon cooling at $-50^{\circ} \mathrm{C}$, red microcrystals were deposited which were filtered off, washed with pentane ( $3 \times 20 \mathrm{~cm}^{3}$ ) and dried under vacuum ( 1305 mg , $73 \%$ (Found: C, $50.45 ; \mathrm{H}, 5.1 ; \mathrm{S}, 18.25 . \mathrm{C}_{44} \mathrm{H}_{54} \mathrm{~N}_{2} \mathrm{~S}_{6} \mathrm{U}$ requires C, $50.75 ; \mathrm{H}, 5.25 ; \mathrm{S}, 18.5 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $\left[{ }^{2} \mathrm{H}_{8}\right]$ thf, $30^{\circ} \mathrm{C}$ ): $\delta 7.4$ $(12 \mathrm{H}, o-\mathrm{Ph}), 6.68(12 \mathrm{H}, m-\mathrm{Ph}), 4.81(6 \mathrm{H}, p-\mathrm{Ph}), 2.56(8 \mathrm{H}, \mathrm{q}, J$ $\left.6, \mathrm{CH}_{2}\right), 1.00\left(12 \mathrm{H}, \mathrm{t}, J 6 \mathrm{~Hz}, \mathrm{CH}_{3}\right)$.
$\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3} \mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right]$ 2.-A round bottomed flask ( $100 \mathrm{~cm}^{3}$ ) was charged with $\mathrm{UCl}_{4}(200 \mathrm{mg}, 0.52$ mmol ), $\mathrm{NaSPh}(278 \mathrm{mg}, 2.1 \mathrm{mmol}), \mathrm{CuSPh}(180 \mathrm{mg}, 1.04 \mathrm{mmol})$ and $\mathrm{PPh}_{3}(262 \mathrm{mg}, 1.0 \mathrm{mmol})$ and thf $\left(50 \mathrm{~cm}^{3}\right)$ was condensed into it at $-78^{\circ} \mathrm{C}$ under vacuum. The red solution was filtered and the red residue extracted in thf $\left(3 \times 20 \mathrm{~cm}^{3}\right)$. After evaporation of the solvent, the red microcrystalline powder was washed with diethyl ether ( $3 \times 10 \mathrm{~cm}^{3}$ ) and dried under vacuum ( $490 \mathrm{mg}, 60 \%$ ) (Found: C, 55.8 ; H, 3.85; S, 12.25. $\mathrm{C}_{72} \mathrm{H}_{60} \mathrm{Cu}_{2} \mathrm{P}_{2} \mathrm{~S}_{6} \mathrm{U}$ requires C, $55.95 ; \mathrm{H}, 3.9 ; \mathrm{S}, 12.45 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $\left.{ }^{2} \mathrm{H}_{8}\right]$ thf, $30^{\circ} \mathrm{C}$ ): $\delta 20.76(12 \mathrm{H}, o-\mathrm{SPh}), 11.43(12 \mathrm{H}, m-$

Crystal-structure Determinations.-Crystals of 1 and 2.6thf were obtained by recrystallization from thf; they were well shaped, with defined edges and faces, but not of simple geometry. Selected single crystals were introduced into thinwalled Lindeman glass tubes; because the crystals of 2.6 thf readily turned opaque in the glove-box, following desolvation, they were selected from the mother-liquor and immediately placed into the tube together with a droplet of thf. Data were collected (at $20^{\circ} \mathrm{C}$ for 1 and $-30^{\circ} \mathrm{C}$ for 2.6 thf) on an EnrafNonius CAD-4 diffractometer equipped with a graphite monochromator $[\lambda(\mathrm{Mo}-\mathrm{K} \alpha)=0.71073 \AA$ ]. The cell parameters were obtained by a least-squares refinement of the setting angles of 25 reflections with $\theta$ between 8 and $12^{\circ}$. Three standard reflections were measured every hour; a decay was observed ( $77 \%$ in 29 h for 1 and $19 \%$ in 27 h for $\mathbf{2} \cdot 6 \mathrm{thf}$ ) and linearly corrected. The data were corrected for Lorentz polarization effects and absorption. ${ }^{21}$ The structure was solved by the heavy-atom method and refined by full-matrix least squares on $F$ with anisotropic parameters for the uranium and sulfur atoms in 1 and for the uranium atom in $2 \cdot 6$ thf. The hydrogen atoms were introduced at calculated positions ( $\mathrm{C}-\mathrm{H} 0.95 \AA$ and $B=6 \AA^{2}$ ); they were not refined but constrained to ride on their parent carbon atom. The asymmetric unit of $\mathbf{2}$.6thf contains three molecules of thf which were difficult to locate accurately, certainly because of their lability; these solvation molecules show large thermal parameters and some erratic bond distances and angles. All calculations were performed on a Vax 4000-200 computer with the Enraf-Nonius MolEN system. ${ }^{22}$ Scattering factors for neutral atoms ${ }^{23}$ were corrected for both $\Delta f^{\prime}$ and $\Delta f^{\prime \prime}$ components of anomalous dispersion. Crystallographic data and experimental details are given in Table 3, final positional parameters in Tables 4 and 5 .

Additional material available from the Cambridge Crystallographic Data Centre comprises thermal parameters and remaining bond lengths and angles.

Table 5 Fractional atomic coordinates with e.s.d.s in parentheses for $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cu}(\mu-\mathrm{SPh})_{3} \mathrm{U}(\mu-\mathrm{SPh})_{3} \mathrm{Cu}\left(\mathrm{PPh}_{3}\right)\right] \cdot 6 \mathrm{thf}$
