

Complexes of the Bidentate Ligands $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNR}_2$ ($\text{R} = \text{Me}$ or H) with Rhodium and Iridium

Sarath D. Perera and Bernard L. Shaw

School of Chemistry, University of Leeds, Leeds LS2 9JT, UK

Treatment of 0.5 equivalent of $[\{\text{RhCl}(\text{CO})_2\}_2]$ with the phosphino dimethylhydrazone $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2(\text{L}^1)$ or the phosphino hydrazone $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2(\text{L}^2)$ gave the chelate complexes $[\text{RhCl}(\text{CO})\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNR}_2\}]$ ($\text{R} = \text{Me}$ **1a** or H **1b**). Complex **1a** reacts with another mole of L^1 to give the bis(phosphine)rhodium(i) complex *trans*- $[\text{RhCl}(\text{CO})\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}_2]$ **2a**. The analogous iridium(i) complex **2b** was prepared by treating $[\text{IrCl}(\text{CO})_2(\text{H}_2\text{NC}_6\text{H}_4\text{Me-}p)]$ with 2 mol equivalents of L^1 . Complex **2a** reacts with $[\text{PtCl}_2(\text{cod})]$ ($\text{cod} = \text{cycloocta-1,5-diene}$) to give a 1:1 mixture of the chelate **1a** and $[\text{PtCl}_2\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$. Treatment of $[\text{IrCl}(\text{CO})_2(\text{H}_2\text{NC}_6\text{H}_4\text{Me-}p)]$ with 2 equivalents of L^2 gave the hydrido-iridium(III) complex *cis*- $[\text{IrH}(\text{Cl})\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2\}_2]\text{Cl}$ **3a**. Treatment of $[\{\text{MCl}(\text{cod})\}_2]$ ($\text{M} = \text{Rh}$ or Ir) with two equivalents of L^1 in methanol in the presence of NH_4PF_6 gave the cationic complexes $[\text{M}(\text{cod})\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]\text{PF}_6$ ($\text{M} = \text{Rh}$ **4a** or Ir **4b**) in which L^1 is bidentate. When $[\{\text{MCl}(\text{cod})\}_2]$ was treated with 2 equivalents of L^1 in benzene it yielded the neutral complexes $[\text{MCl}(\text{cod})\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$ ($\text{M} = \text{Rh}$ **5a** or Ir **5b**) in which L^1 is monodentate through phosphorus. Treatment of $[\{\text{MCl}(\text{cod})\}_2]$ with 2 equivalents of L^2 in CD_2Cl_2 gave the cationic chelate complexes $[\text{M}(\text{cod})\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2\}_2]\text{Cl}$ ($\text{M} = \text{Rh}$ **4c** or Ir **4d**). Treatment of $[\{\text{RhCl}(\text{cod})\}_2]$ or $[\{\text{RhCl}(\text{C}_8\text{H}_{14})_2\}_2]$ ($\text{C}_8\text{H}_{14} = \text{cyclooctene}$) with 2 equivalents of L^2 per rhodium atom gave the cationic bis(phosphine)rhodium(i) complex $[\text{Rh}\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2\}_2]\text{Cl}$ **6**. Treatment of $[\text{RhCl}(\text{PPh}_3)_3]$ with 1 equivalent of L^1 in C_6D_6 gave the Wilkinson-type complex $[\text{RhCl}(\text{PPh}_3)_2\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$ **7**, which readily reacts with dioxygen to give the adduct *cis*- $[\text{RhCl}(\text{O}_2)(\text{PPh}_3)_2\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$ **8**. The rhodium(III) complex **8** reacts with sulfur dioxide to give the rhodium(III) sulfate *cis*- $[\text{RhCl}(\text{SO}_4)(\text{PPh}_3)_2\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$ **9**. Treatment of $[\{\text{MCl}(\text{C}_8\text{H}_{14})_2\}_2]$ with 2 equivalents of L^1 per rhodium atom gave the bis(phosphine) complexes *cis*- $[\text{MCl}\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}_2\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$ ($\text{M} = \text{Rh}$ **10a** or Ir **10b**), containing one chelate and one monodentate phosphine ligand. These complexes reacted rapidly with dioxygen to give corresponding dioxygen adducts *cis*- $[\text{MCl}(\text{O}_2)\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}_2\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2\}]$ ($\text{M} = \text{Rh}$ **11a** or Ir **11b**). Proton, $^{31}\text{P}\{-^1\text{H}\}$ and some $^{13}\text{C}\{-^1\text{H}\}$ NMR data are given.

In a previous paper¹ we reported the synthesis of *Z-tert*-butyl diphenylphosphinomethyl ketone dimethylhydrazone, $Z\text{-PPh}_2\text{-CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2(\text{L}^1)$ and *Z-tert*-butyl diphenylphosphinomethyl ketone hydrazone, $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2(\text{L}^2)$. We have described the complexes and subsequent chemistry of these bidentate (P,N) ligands L^1 and L^2 with Cr^0 , Mo^0 and W^0 ,¹ and more recently with Pd^{II} and Pt^{II} .² We have also used L^2 as a 'reagent' for derivatising aldehydes and ketones, $\text{R}'\text{C}(=\text{O})\text{R}''$ ($\text{R}' = \text{H}$ or Me , $\text{R}'' = \text{aryl}$, alkyl , alkenyl or heterocyclic radical), as azines of type $\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{N}-\text{N}=\text{CR}'\text{R}''$. By complexing the azines to metals, one of the R groups becomes compressed against the metal which promoted agostic C-H interaction,³ C-F co-ordination,⁴ C-H bond fission⁵ or C-X bond fission ($\text{X} = \text{I}$, Br , Cl ⁶ or F ⁷). In the present paper we describe the synthesis and characterisation of some rhodium and iridium complexes containing L^1 or L^2 and other ligands such as carbon monoxide, cycloocta-1,5-diene, triphenylphosphine or dioxygen. There is increasing interest in the use of bidentate (P,N) compounds to generate new co-ordination, organometallic or catalytic chemistry.⁸⁻²¹ Some examples with rhodium or iridium include *o*- $\text{PPh}_2\text{C}_6\text{H}_4(\text{CH}_2)_n\text{NMe}_2$ ($n = 0$ or 1),^{14,15} $\text{PPh}_2(\text{CH}_2)_n\text{NMe}_2$ ($n = 2$ or 3),¹⁵ *o*- $\text{PPh}_2\text{C}_6\text{H}_4\text{-NH}_2$,¹⁶ *o*- $\text{PPh}_2\text{C}_6\text{H}_4\text{NHR}$ ($\text{R} = \text{Et}$ or CH_2Ph),¹⁷ $\text{PPh}_2\text{-}(\text{CH}_2)_2(2\text{-C}_5\text{H}_4\text{N})$ ¹⁸ and *o*- $\text{PPh}_2\text{C}_6\text{H}_4\text{CH}=\text{NR}$ ($\text{R} = \text{Et}$, Pr^n , Pr^i or Bu^i).^{19,20}

Results and Discussion

For the convenience of the reader the phosphine ligands L^1 and L^2 , and the complexes prepared from them, are shown in Schemes 1-4. Elemental analyses, and some mass spectral and infrared data are in the Experimental section, $^{31}\text{P}\{-^1\text{H}\}$ and $^{13}\text{C}\{-^1\text{H}\}$ NMR data in Table 1, and ^1H NMR data in Table 2. Some of the complexes are very air-sensitive^{16,17,22} and were characterised by ^1H and $^{31}\text{P}\{-^1\text{H}\}$ NMR spectroscopy, only.

Treatment of L^1 with 0.5 mol equivalent of the binuclear rhodium(i) complex $[\{\text{RhCl}(\text{CO})_2\}_2]$ gave a single product **1a** with a six-membered chelate ring and phosphorus *trans* to chlorine. There are several pieces of evidence, indicative of the formation of a six-membered chelate ring, *i.e.* with NMe_2 co-ordinated. The shifts to low field of the methyl protons of the NMe_2 group on co-ordination ($\Delta\delta_{\text{H}} \approx +0.9$ ppm) and also the carbon-13 shifts of the NMe_2 methyls ($\Delta\delta_{\text{C}} \approx +5.5$ ppm) suggest that the NMe_2 nitrogen is co-ordinated to rhodium. Similar co-ordination shifts have been found for *o*-(diphenylphosphino)-*N,N*-dimethylaniline, (*o*- $\text{PPh}_2\text{C}_6\text{H}_4\text{NMe}_2$) on chelation to rhodium.¹⁴ Additionally, the carbon-13 chemical shift (δ_{C}) for the CH_2 group is 21.2, typical of a six-membered chelate ring.^{2,6,23,24} The $^{31}\text{P}\{-^1\text{H}\}$ NMR data, $\delta_{\text{P}} = 54.4$ with $^1J(\text{RhP}) = 178$ Hz, are typical of phosphorus *trans* to chlorine^{15,18,22,25,26} and the value of $^2J(\text{PC})$ of 18 Hz for the

Table 1 $^{31}\text{P}\{-^1\text{H}\}^a$ and $^{13}\text{C}\{-^1\text{H}\}$ NMR data^b

^a Recorded at 36.2 MHz, chemical shifts in ppm relative to 85% H₃PO₄, $^1J(\text{RhP})$ values in Hz, solvent CDCl₃ unless otherwise stated. ^b Recorded at 100.6 MHz, chemical shifts in ppm relative to SiMe₄, J values in Hz, solvent CDCl₃ unless otherwise stated; C_i, C_o, C_m and C_p refer to *ipso*-, *ortho*-, *meta*- and *para*-carbons of the PPh₂ group.

C=O ligand suggests that C=O is *cis* to phosphorus.^{26,27} The $\nu(\text{C}=\text{O})$ value of 1995 cm⁻¹ is similar to values reported for carbonylrhodium(i) complexes.^{15,18,28}

Similar treatment of the rhodium(i) complex [$\{\text{RhCl}(\text{CO})_2\}_2$] with 2 equivalents of L² gave the corresponding chelate complex **1b** in excellent (89%) yield. This was characterised in a similar fashion to **1a**. A proton NMR study in which a CDCl₃ solution of **1b** was shaken with D₂O caused rapid exchange of the NH₂ protons for deuterons.

Treatment of [$\{\text{RhCl}(\text{CO})_2\}_2$] with 2 equivalents of L¹ per rhodium atom gave the *trans*-chloro(carbonyl)rhodium(i) complex **2a**, which was also prepared by treating the chelate complex **1a** with 1 mol equivalent of L¹ *via* a ring-opening

reaction. For **2a** the $^1J(\text{RhP})$ value of 130 Hz is typical for complexes of type *trans*-[RhCl(CO)(PR₃)₂].²⁹⁻³¹ In the proton NMR spectrum the value of $\delta_{\text{H}}(\text{NMe}_2)$ 1.93 is similar to that of the free hydrazone (2.10) and quite different to the value when NMe₂ is co-ordinated, *i.e.* δ 3.03 for the chelate complex **1a**. In the $^{13}\text{C}\{-^1\text{H}\}$ NMR spectrum of **2a** the resonances for CH₂, C=N and C_o, C_m and C_p carbons of the phenyl rings are virtual 1:2:1 triplets,³¹ whilst C=O appears as a doublet of triplets (Table 1). The bis(phosphine) complex **2a** when treated with 1 equivalent of [PtCl₂(cod)] (cod = cycloocta-1,5-diene) reacted rapidly to give a 1:1 mixture of the chelate complexes **1a** and [PtCl₂{PPh₂CH₂C(Bu)¹=NNMe₂}]₂ (Scheme 1).

Treatment of [IrCl(CO)₂(H₂NC₆H₄Me-*p*)] with 2 mol

^a Recorded at 100 MHz, chemical shifts (δ) in ppm relative to SiMe₄, solvent CDCl₃ unless otherwise stated, coupling constants *J* in Hz; s = singlet, d = doublet, dd = doublet of doublets, fd = apparent filled-in doublet, t = triplet, vt = virtual triplet and br = broad. ^b Observed weak coupling to phosphorus and exchange with D₂O. ^c *N* = |²J(PH) + ⁴J(PH)|. ^d In C₆D₆. ^e In CD₂Cl₂. ^f Recorded at 400 MHz. ^g Resonances due to cod appeared as multiplets at δ 2.03 (2 H), 2.20 (2 H), 2.30 (2 H), 2.56 (2 H), 3.22 (2 H) and 5.55 (2 H). ^h Resonances due to cod appeared as multiplets at δ 1.78 (2 H), 2.00 (2 H), 2.08 (2 H), 2.38 (2 H), 3.00 (2 H) and 5.21 (2 H). ⁱ Resonances due to cod appeared as broad peaks at δ 1.95–2.50 (8 H), 4.22 (2 H) and 4.52 (2 H). ^j Resonances due to cod appeared as broad peaks at δ 1.68 (4 H), 2.19 (4 H) and 3.62 (4 H). ^k Resonances due to NH₂ were not observed. ^l Resonances due to cod appeared as broad peaks at δ 1.85 (2 H), 2.00 (2 H), 2.34 (4 H), 2.91 (2 H) and 5.46 (2 H). ^m Resonances due to cod appeared as broad peaks at δ 1.63 (4 H), 2.13 (4 H) and 3.67 (4 H). ⁿ Obscured by other peaks.

equivalents of L¹ gave the bis(phosphine) complex **2b** in good (78%) yield. The characterising data show that this Vaska-type iridium(i) complex is analogous to the rhodium(i) complex **2a**, i.e. the phosphine ligands are monodentate through phosphorus and mutually *trans*. The $\nu(\text{C}=\text{O})$ value of 1955 cm⁻¹ is similar to literature values for carbonyliridium(i) complexes of the type *trans*-[IrCl(CO)(PR₃)₂].^{18,32}

Treatment of [IrCl(CO)₂(H₂NC₆H₄Me-*p*)] with 2 mol equivalents of L² gave the hydrido-iridium(iii) salt **3a** (Scheme 2), i.e. the carbonyl ligand was displaced. The mother-liquors from this reaction were very dark brown and we were unable to isolate any other product from them. We suggest that the source of hydride is an NH hydrogen from *p*-toluidine or from the hydrazone L². This chloride salt **3a** was converted into the corresponding mixed chloride-tetraphenylborate salt **3b**, when treated with NaBPh₄. The ³¹P-{¹H} NMR data for **3a** or **3b** show a singlet resonance (i.e. the two phosphorus nuclei are chemically equivalent) whilst the hydride resonance is a triplet at $\delta \approx -21.5$ with a ²J(PH) value of 16.5 Hz, and $\nu(\text{Ir}-\text{H})$ at 2210 cm⁻¹.¹⁷ The hydride must therefore be *trans* to chloride. As would be expected the CH₂ resonance in the ¹H-{³¹P} NMR spectrum is an AB pattern with ²J(HH) = 13.2 Hz. The NH₂ protons also showed an AB pattern with ²J(HH) = 13.2 Hz. In the ¹³C-{¹H} NMR spectrum the carbon-13 resonances for CH₂, C=N, and C_o, C_m and C_p carbons of the phenyl rings are

doublets suggesting that the two phosphorus donor atoms are not strongly coupled and are therefore mutually *cis*. We have reported that palladium(ii) or platinum(ii) centres react with 2 mol of L² to give bis(chelate) complexes of type *cis*-[M{PPh₂CH₂C(Bu)¹=NNH₂}]₂²⁺ (M = Pd or Pt).²

Treatment of the binuclear complex [RhCl(cod)]₂ with 2 mol equivalents of L¹ in methanol in the presence of NH₄PF₆ gave the hoped for cationic cycloocta-1,5-diene complex **4a** (Scheme 3). The ¹H and ¹³C-{¹H} NMR data [e.g. $\delta_{\text{H}}(\text{NMe}_2) = 3.06$ and $\delta_{\text{C}}(\text{NMe}_2) = 52.8$] clearly indicate the co-ordination of the NMe₂ nitrogen to rhodium. The P,N chelation is also supported by the observation of a downfield ring shift¹⁷ ($\Delta\delta_{\text{p}} \approx 26$ ppm) in the phosphorus-31 resonance ($\delta_{\text{p}} 47.5$) of **4a** when compared to the phosphorus-31 chemical shift of complex **5a** ($\delta_{\text{p}} 21.4$, see below) in which the phosphine ligand L¹ is monodentate. The analogous cationic iridium(i) complex **4b** was similarly prepared and fully characterised.

Treatment of [MCl(cod)]₂ (M = Rh or Ir) with L¹ in benzene gave the neutral cycloocta-1,5-diene complex **5a** (Rh) or **5b** (Ir), respectively in which L¹ is monodentate. The complexes were characterised by ³¹P-{¹H} and ¹H NMR spectroscopy (Tables 1 and 2) and **5a** additionally by ¹³C-{¹H} NMR spectroscopy. The proton, ³¹P-{¹H} and ¹³C-{¹H} NMR spectra clearly show that the NMe₂ is not co-ordinated in these

Scheme 2 (i) 0.5 equivalent $[\text{IrCl}(\text{CO})_2(\text{H}_2\text{NC}_6\text{H}_4\text{Me-}p)]$; (ii) NaBPh_4

complexes. The value of $^1J(\text{RhP})$ of 152 Hz is typical for a complex of type $[\text{RhCl}(\text{diene})(\text{PR}_3)_2]$.^{17,22,25,33}

The chelating phosphine cycloocta-1,5-diene salts **4c** (Rh) or **4d** (Ir) from L^2 were prepared *in situ* by treating the appropriate complex $[\{\text{MCl}(\text{cod})\}_2]$ ($\text{M} = \text{Rh}$ or Ir) with L^2 in CD_2Cl_2 solution. These chelate complexes **4c** and **4d** are extremely air-sensitive. Treatment of $[\{\text{RhCl}(\text{cod})\}_2]$ with 1 mol equivalent of L^2 per rhodium atom gave salt **4c** which when treated with a second mol of L^2 gave the bis(chelate) salt *cis*- $[\text{Rh}\{\text{PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2\}_2]\text{Cl}$ **6**. We assign a *cis* geometry to the bis(chelate) ligands from the value of $^1J(\text{RhP})$ of 191 Hz, typical of phosphorus *trans* to nitrogen, and in the ^1H NMR spectrum the CH_2 resonance is of a 'filled in' doublet type with $N = 9.3$ Hz suggesting that $^2J(\text{PP})$ is not large and that the phosphorus donor atoms are not mutually *trans*.^{2,31} We also made the bis(chelate) salt **6** by treating L^2 with 0.25 equivalent of the complex $[\{\text{RhCl}(\text{C}_8\text{H}_{14})_2\}_2]$ ($\text{C}_8\text{H}_{14} = \text{cyclooctene}$).

We also studied the action of L^1 on the Wilkinson catalyst $[\text{RhCl}(\text{PPh}_3)_3]$ (Scheme 4). Treatment with 1 mol of L^1 displaced two triphenylphosphine ligands and gave the hoped for chelate triphenylphosphine complex **7**. This was very air-sensitive and only characterised by NMR spectroscopy in C_6D_6

Scheme 3 (i) 0.5 equivalent $[\{\text{MCl}(\text{cod})\}_2]$ and NH_4PF_6 in MeOH ; (ii) 0.5 equivalent $[\{\text{MCl}(\text{cod})\}_2]-\text{C}_6\text{H}_6$; (iii) 0.5 equivalent $[\{\text{RhCl}(\text{cod})\}_2]-\text{CD}_2\text{Cl}_2$; (iv) L^2 ; (v) 0.25 equivalent $[\{\text{RhCl}(\text{cod})\}_2]-\text{CD}_2\text{Cl}_2$; (vi) 0.5 equivalent $[\{\text{IrCl}(\text{cod})\}_2]-\text{CD}_2\text{Cl}_2$

solution. The $^{31}\text{P}-\{^1\text{H}\}$ NMR data [$^2J(\text{PP}) = 46$ Hz] indicated that the two phosphorus nuclei were mutually *cis*. The resonances were assigned to P_A (the chelate) and P_B (PPh_3) on the basis of selective decoupling which established that the CH_2 protons were coupled to P_A only [$^2J(\text{P}_A\text{H}) = 11.2$ Hz]. The ^1H NMR spectrum suggested from the value of $\delta(\text{NMe}_2)$ 3.49 that the NMe_2 nitrogen is co-ordinated to rhodium. A benzene solution of this Wilkinson-type complex **7**, prepared *in situ*, reacted with dioxygen (or air) to give the pale yellow dioxygen adduct **8** in 95% isolated yield. This dioxygen adduct was fully characterised, by C, H, N and Cl analysis, ^1H , $^{13}\text{C}-\{^1\text{H}\}$ and $^{31}\text{P}-\{^1\text{H}\}$ NMR and mass spectroscopy. In the mass spectrum the parent molecular ion ($M + 1$) was readily observed as were the other ions corresponding to loss of dioxygen, and dioxygen and chlorine. In the infrared spectrum (KBr) there is a band at 870 cm^{-1} , assigned to $\nu(\text{O}-\text{O})$.³⁴⁻³⁷ As would be expected in the ^1H NMR spectrum the CH_2 protons are non-equivalent and mutually coupled [$^2J(\text{HH}) = 13.9$ Hz], and they are coupled only to P_A . In contrast, the NMe_2 hydrogens are coupled only to P_B suggesting that the NMe_2 group is *trans* to P_B ,^{4,28} the methyls being non-equivalent with $^4J(\text{P}_B\text{Me}) = 2.2$ and 2.4 Hz, respectively. The dioxygenrhodium(III) complex **8** reacted rapidly with sulfur dioxide to give the rhodium(III) sulfate **9** in 76% isolated yield. Complex **9** was fully characterised. In the

Scheme 4 (i) $[RhCl(PPh_3)_3]$; (ii) O_2 ; (iii) SO_2 ; (iv) 0.25 equivalent $[MCl(C_8H_{14})_2]_2$

infrared spectrum the bands due to $\nu(SO_4)$ at 1260, 1160 and 655 cm^{-1} are at similar frequencies to those found for other bidentate sulfur complexes.^{19,37}

Treatment of $[RhCl(C_8H_{14})_2]_2$ with 2 mol equivalents of L^1 per rhodium atom gave the bis(phosphine)rhodium(I) complex **10a**, containing one chelate and one monodentate $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2$ ligand. This complex was characterised by elemental analysis and mass spectrometry and by $^{31}\text{P}\text{-}\{^1\text{H}\}$ and ^1H NMR spectroscopy. In particular, in the $^{31}\text{P}\text{-}\{^1\text{H}\}$ NMR spectrum the value of $^2J(\text{PP})$ of 44 Hz indicates mutually *cis*-phosphine ligands, and the $^1J(\text{RhP})$ values of 218 and 179 Hz are similar to those of **7**. In the ^1H NMR spectrum there are two sets of Bu^t , CH_2 and NMe_2 protons, corresponding to chelating and monodentate $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2$ ligands, respectively. The singlet at δ 1.56 is assigned to the un-co-ordinated NMe_2 group. Treatment of complex **10a** with a one-third mol of L^1 did not result in a ring-opening reaction to give a complex of type $[RhCl(L^1)_3]$ at 20°C in benzene solution.

An analogous bis(phosphine)iridium(I) complex **10b** was prepared *in situ* and characterised in solution. From the NMR data it is clearly analogous to the bis(phosphine)rhodium(I) complex **10a**. Complex **10a** or **10b** in dichloromethane solution reacted rapidly with dioxygen to give the corresponding dioxygen adduct **11a** or **11b**, respectively, both of which were isolated and characterised.

Experimental

All the reactions were carried out in an inert atmosphere of dry nitrogen or dry argon. Infrared spectra were recorded using a Perkin-Elmer model 457 grating spectrometer, NMR spectra using a JEOL FX-90Q (operating frequencies for ^1H and ^{31}P of

89.5 and 36.2 MHz), FX-100 (operating frequencies for ^1H and ^{31}P of 99.5 and 40.25 MHz) or a Bruker AM-400 spectrometer (operating frequencies for ^1H , ^{31}P and ^{13}C of 400.13, 161.9 and 100.6 MHz), respectively. The ^1H and ^{13}C chemical shifts are relative to tetramethylsilane and ^{31}P shifts to 85% phosphoric acid. Fast atom bombardment (FAB) mass spectra were recorded on a VG Autospec spectrometer using 8 kV acceleration. For metal complexes m/z values are quoted for ^{35}Cl , ^{103}Rh and ^{193}Ir .

The compounds $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNMe}_2$ L^1 and $Z\text{-PPh}_2\text{CH}_2\text{C}(\text{Bu}^t)=\text{NNH}_2$ L^2 were prepared according to our published procedure;¹ $[RhCl(CO)_2]_2$,³⁸ $[IrCl(CO)_2(H_2NC_6H_4Me-p)]$,³⁹ $[RhCl(cod)]_2$,⁴⁰ $[RhCl(PPh_3)_3]$,⁴¹ $[IrCl(cod)]_2$,⁴² $[IrCl(C_8H_{14})_2]_2$ ⁴² and $[RhCl(C_8H_{14})_2]_2$ ⁴³ were prepared according to literature procedures.

[RhCl(CO){PPh₂CH₂C(Bu^t)=NNMe₂}] 1a.—The complex $[RhCl(CO)_2]_2$ (75 mg, 0.19 mmol) was added to a solution of the phosphino hydrazone L^1 (126 mg, 0.38 mmol) in benzene (3 cm^3). After 10 min the resulting yellow solution was concentrated to a low volume (*ca.* 0.5 cm^3) under reduced pressure and the residue triturated with methanol to give the required product **1a** as yellow microcrystals (144 mg, 76%) (Found: C, 51.15; H, 5.5; Cl, 7.4; N, 5.7. $C_{21}H_{27}ClN_2OPRh$ requires C, 51.2; H, 5.2; Cl, 7.2; N, 5.7%). m/z (FAB) 466 ($M - \text{CO}$) and 457 ($M - \text{Cl}$); $IR(\text{CH}_2\text{Cl}_2)$: $\nu(\text{C}=\text{O})\ 1995\text{ cm}^{-1}$.

[RhCl(CO){PPh₂CH₂C(Bu^t)=NNH₂}] 1b.—The complex $[RhCl(CO)_2]_2$ (75 mg, 0.19 mmol) was added to a solution of the phosphino hydrazone L^2 (111 mg, 0.37 mmol) in benzene (3 cm^3). After 10 min the resulting yellow solution was concentrated to a low volume (*ca.* 0.5 cm^3) under reduced pressure. Addition of hexane to the residue gave the required product **1b** as yellow microcrystals (155 mg, 89%) (Found: C, 49.05; H, 5.05; Cl, 7.65; N, 5.65. $C_{19}H_{23}ClN_2OPRh$ requires C, 49.1; H, 5.0; Cl, 7.65; N, 6.0%). m/z (FAB) 437 ($M + 1 - \text{CO}$); $IR(\text{CH}_2\text{Cl}_2)$: $\nu(\text{C}=\text{O})\ 1995\text{ cm}^{-1}$.

trans-[RhCl(CO){PPh₂CH₂C(Bu^t)=NNMe₂}]₂ 2a.—The complex $[RhCl(CO)_2]_2$ (50 mg, 0.13 mmol) was added to a solution of L^1 (168 mg, 0.51 mmol) in benzene (3 cm^3). After 10 min the resulting yellow solution was filtered and concentrated to a low volume (*ca.* 0.5 cm^3) under reduced pressure. Addition of hexane (2 cm^3) to the residue gave the required product **2a** as pale yellow microcrystals (170 mg, 80%) (Found: C, 60.95; H, 6.75; Cl, 4.25; N, 6.6. $C_{41}H_{54}ClN_4OP_2Rh \cdot 0.25C_6H_6$ requires C, 60.85; H, 6.65; Cl, 4.25; N, 6.7%). m/z (FAB) 819 ($M + 1$), 783 ($M - \text{Cl}$) and 755 ($M - \text{Cl} - \text{CO}$); $IR(\text{CH}_2\text{Cl}_2)$: $\nu(\text{C}=\text{O})\ 1960\text{ cm}^{-1}$.

trans-[IrCl(CO){PPh₂CH₂C(Bu^t)=NNMe₂}]₂ 2b.—The complex $[IrCl(CO)_2(H_2NC_6H_4Me-p)]$ (75 mg, 0.19 mmol) was added to a solution of L^1 (126 mg, 0.39 mmol) in benzene (4 cm^3) and the solution was warmed to *ca.* 70°C for 1 min. The solution was then filtered and concentrated to a low volume (*ca.* 0.5 cm^3) under reduced pressure. Addition of hexane (2 cm^3) to the residue gave the required product **2b** as yellow microcrystals (135 mg, 78%) (Found: C, 54.4; H, 6.0; Cl, 4.0; N, 6.0. $C_{41}H_{54}ClIrN_4OP_2$ requires C, 54.2; H, 6.0; Cl, 3.9; N, 6.15%). m/z (FAB) 909 ($M + 1$) and 873 ($M - \text{Cl}$); $IR(\text{CH}_2\text{Cl}_2)$: $\nu(\text{C}=\text{O})\ 1955\text{ cm}^{-1}$.

cis-[IrH(Cl){PPh₂CH₂C(Bu^t)=NNH₂}]₂Cl 3a.—The complex $[IrCl(CO)_2(H_2NC_6H_4Me-p)]$ (100 mg, 0.25 mmol) and L^2 (150 mg, 0.50 mmol) in benzene (4 cm^3) were heated under reflux for 15 min. The resulting white precipitate of **3a** was filtered off, washed with hexane and dried. Yield 105 mg, 97% with respect to chlorine (Found: C, 50.0; H, 5.5; Cl, 7.95; N, 6.65. $C_{36}H_{47}Cl_2IrN_4P_2$ requires C, 50.2; H, 5.5; Cl, 8.25; N, 6.5%). m/z (FAB) 825 ($M - \text{Cl}$) and 789 ($M - \text{Cl} - \text{HCl}$); $IR(\text{KBr})$: $\nu(\text{Ir-H})\ 2210\text{ cm}^{-1}$.

cis-[IrH(Cl){PPh₂CH₂C(Bu')=NNH₂}₂][BPh₄]_{0.6}Cl_{0.4} **3b**.—An excess of NaBPh₄ (100 mg, 0.29 mmol) in ethanol (1 cm³) was added to a solution of the chloride salt **3a** (50 mg, 0.058 mmol) in ethanol (1.5 cm³). The required product **3b** was obtained as a white solid (42 mg, 64%) (Found: C, 60.3; H, 5.65; Cl, 4.05; N, 4.85. C₃₆H₄₄IrN₄P₂·0.6C₂₄H₂₀B·0.4Cl requires C, 60.1; H, 5.65; Cl, 4.05; N, 4.85%). *m/z* (FAB) 825 (*M* - BPh₄/Cl) and 789 (*M* - BPh₄/Cl - HCl); IR(KBr): ν(Ir-H) 2210 cm⁻¹.

[Rh(cod){PPh₂CH₂C(Bu')=NNMe₂}]₂PF₆ **4a**.—An excess of NH₄PF₆ (0.2 g, 1.2 mmol) in methanol (*ca.* 1 cm³) was added to a solution containing [RhCl(cod)]₂ (125 mg, 0.25 mmol) and L¹ (165 mg, 0.50 mmol) in methanol (3 cm³). The resulting yellow crystals of complex **4a** were filtered off, washed with cold methanol and dried. Yield 0.31 g, 91% (Found: C, 49.6; H, 5.65; N, 4.1. C₂₈H₃₉F₆N₂P₂Rh requires C, 49.3; H, 5.75; N, 4.1%). *m/z* (FAB) 537 (*M* - PF₆).

[Ir(cod){PPh₂CH₂C(Bu')=NNMe₂}]₂PF₆ **4b**.—Complex **4b** was prepared from [IrCl(cod)]₂ and isolated in 35% yield as orange microcrystals in a similar manner to the analogous rhodium(i) complex **4a**. An analytical sample was recrystallised from benzene-methanol (Found: C, 44.75; H, 5.05; N, 3.5. C₂₈H₃₉F₆IrN₂P₂·0.25C₆H₆ requires C, 44.75; H, 5.15; N, 3.55%). *m/z* (FAB) 627 (*M* - PF₆).

[Rh(cod){PPh₂CH₂C(Bu')=NNH₂}]₂Cl **4c**.—Complex **4c** was prepared *in situ* by dissolving [RhCl(cod)]₂ (15 mg, 0.03 mmol) and L² (17 mg, 0.057 mmol) in CD₂Cl₂ (*ca.* 0.4 cm³).

[Ir(cod){PPh₂CH₂C(Bu')=NNH₂}]₂Cl **4d**.—Complex **4d** was prepared *in situ* by dissolving [IrCl(cod)]₂ (10 mg, 0.015 mmol) and L² (8.9 mg, 0.03 mmol) in CD₂Cl₂ (*ca.* 0.4 cm³).

[RhCl(cod){PPh₂CH₂C(Bu')=NNMe₂}]₂ **5a**.—The complex [RhCl(cod)]₂ (50 mg, 0.10 mmol) and L¹ (66 mg, 0.20 mmol) were dissolved in benzene (3 cm³). After 15 min the solution was concentrated to a low volume (*ca.* 0.3 cm³) under reduced pressure. Addition of hexane (1 cm³) to the residue gave the required product **5a** as bright yellow microcrystals (80 mg, 70%) (Found: C, 58.05; H, 6.45; Cl, 6.35; N, 4.5. C₂₈H₃₉ClN₂PRh requires C, 58.7; H, 6.85; Cl, 6.2; N, 4.9%). *m/z* (FAB) 573 (*M* + 1) and 537 (*M* - Cl).

[IrCl(cod){PPh₂CH₂C(Bu')=NNMe₂}]₂ **5b**.—The complex [IrCl(cod)]₂ (67 mg, 0.10 mmol) and L¹ (66 mg, 0.20 mmol) were heated under reflux in benzene (4 cm³) for 20 min. The solution was then filtered and the filtrate concentrated to a low volume (*ca.* 0.3 cm³) under reduced pressure. Addition of hexane (2 cm³) to the residue gave the required product **5b** as bright yellow microcrystals (53 mg, 40%) (Found: C, 50.8; H, 5.85; Cl, 5.5; N, 4.35. C₂₈H₃₉ClIrN₂P requires C, 50.75; H, 5.95; Cl, 5.35; N, 4.2%). *m/z* (FAB) 663 (*M* + 1) and 627 (*M* - Cl).

cis-[Rh{PPh₂CH₂C(Bu')=NNH₂}₂]Cl **6**.—(i) From [RhCl(cod)]₂. Complex **6** was prepared *in situ* by dissolving [RhCl(cod)]₂ (15 mg, 0.03 mmol) and L² (37 mg, 0.057 mmol) in CD₂Cl₂ (*ca.* 0.5 cm³).

(ii) From [RhCl(C₈H₁₄)₂]₂. Complex **6** was prepared *in situ* by dissolving [RhCl(C₈H₁₄)₂]₂ (15 mg, 0.021 mmol) and L² (25 mg, 0.084 mmol) in CD₂Cl₂ (*ca.* 0.5 cm³).

cis-[RhCl(PPh₃){PPh₂CH₂C(Bu')=NNMe₂}]₂ **7**.—Complex **7** was prepared *in situ* by dissolving [RhCl(PPh₃)] (15 mg, 0.016 mmol) and L¹ (5.3 mg, 0.016 mmol) in C₆D₆ (*ca.* 0.5 cm³).

cis-[RhCl(O₂)(PPh₃){PPh₂CH₂C(Bu')=NNMe₂}]₂ **8**.—Dioxygen was bubbled for 2 min through a solution containing [RhCl(PPh₃)₃] (0.24 g, 0.26 mmol) and L¹ (84 mg, 0.26 mmol)

in benzene (5 cm³), and the solution was then concentrated to a low volume (*ca.* 0.5 cm³) under reduced pressure. Addition of cyclohexane (2 cm³) to the residue gave the required product **8** as yellow microcrystals (0.19 g, 95%) (Found: C, 59.75; H, 5.45; Cl, 4.8; N, 3.45. C₃₈H₄₂ClN₂O₂P₂Rh requires C, 60.1; H, 5.5; Cl, 4.65; N, 3.7%). *m/z* (FAB) 759 (*M* + 1), 726 (*M* - 2O) and 691 (*M* - 2O - Cl); IR(KBr): ν(O-O) 870 cm⁻¹.

cis-[RhCl(SO₄)(PPh₃){PPh₂CH₂C(Bu')=NNMe₂}]₂ **9**.—Sulfur dioxide was bubbled for 30 s through a solution containing complex **7** (50 mg, 0.065 mmol) in CH₂Cl₂ (1.5 cm³). After 30 min the solution was concentrated to a low volume (*ca.* 0.3 cm³) under reduced pressure. Addition of hexane (1 cm³) to the residue gave the required product **9** as yellow microcrystals (41 mg, 76%) (Found: C, 55.25; H, 5.05; Cl, 4.5; N, 3.4. C₃₈H₄₂ClN₂O₄P₂RhS requires C, 55.45; H, 5.15; Cl, 4.3; N, 3.4%). *m/z* (FAB) 823 (*M* + 1), 786 (*M* - HCl) and 725 (*M* - HSO₄); IR(KBr): ν(SO₄) 1260m, 1160s and 655s cm⁻¹.

cis-[RhCl{PPh₂CH₂C(Bu')=NNMe₂}]₂{PPh₂CH₂C(Bu')=NNMe₂} **10a**.—The complex [RhCl(C₈H₁₄)₂]₂ (30 mg, 0.042 mmol) and L¹ (55 mg, 0.167 mmol) were warmed in acetone (2 cm³) for 1 min. The resulting yellow solution was then cooled to -30 °C. The required product **10a** deposited as orange crystals (47 mg, 71%) (Found: C, 60.65; H, 7.35; Cl, 4.25; N, 6.25. C₄₀H₅₄ClN₄P₂Rh·C₃H₆O requires C, 60.8; H, 7.1; Cl, 4.15; N, 6.6%). *m/z* (FAB) 790 (*M* + 1) and 755 (*M* - Cl).

cis-[IrCl{PPh₂CH₂C(Bu')=NNMe₂}]₂{PPh₂CH₂C(Bu')=NNMe₂} **10b**.—Complex **10a** was prepared *in situ* by dissolving [IrCl(C₈H₁₄)₂]₂ (15 mg, 0.016 mmol) and L¹ (22 mg, 0.067 mmol) in CD₂Cl₂ (*ca.* 0.5 cm³).

cis-[RhCl(O₂){PPh₂CH₂C(Bu')=NNMe₂}]₂{PPh₂CH₂C(Bu')=NNMe₂} **11a**.—Dioxygen was bubbled for 1 min through a solution containing [RhCl(C₈H₁₄)₂]₂ (90 mg, 0.125 mmol) and L¹ (165 mg, 0.50 mmol) in CH₂Cl₂ (4 cm³). The solution was then concentrated to a low volume (*ca.* 0.5 cm³) under reduced pressure. Addition of hexane (3 cm³) to the residue gave the required product **11a** as brown microcrystals (0.16 g, 77%) (Found: C, 56.55; H, 6.7; Cl, 7.85; N, 6.45. C₄₀H₅₄ClN₄O₂P₂Rh·0.5CH₂Cl₂ requires C, 56.2; H, 6.4; Cl, 8.2; N, 6.45%). *m/z* (FAB) 823 (*M* + 1); IR(KBr): ν(O-O) 865 cm⁻¹.

cis-[IrCl(O₂){PPh₂CH₂C(Bu')=NNMe₂}]₂{PPh₂CH₂C(Bu')=NNMe₂} **11b**.—Complex **11b** was prepared using [IrCl(C₈H₁₄)₂]₂ in a similar manner to that of **11a**, in 45% yield (Found: C, 52.65; H, 5.8; Cl, 3.8; N, 6.0. C₄₀H₅₄ClIrN₄O₂P₂ requires C, 52.65; H, 5.95; Cl, 3.9; N, 6.15%). *m/z* (FAB) 913 (*M* + 1); IR(KBr): ν(O-O) 860 cm⁻¹.

Acknowledgements

We thank the SERC for a fellowship (to S. D. P.) and for other support, and Johnson Matthey for a generous loan of platinum metal salts.
