#### Abstract

The unsaturated triosmium cluster $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right]$ reacted with the complex trans- $\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right]$ ( $\mathrm{py}=$ pyridine) to give a range of complexes including $\left[\mathrm{Os}_{s} \mathrm{Pd}(\mathrm{CO})_{18}(\mu-\mathrm{H})_{6}\right] \quad 1 .\left[\mathrm{Os} \mathrm{s}_{5} \mathrm{Pd}(\mathrm{CO})_{14}{ }_{16}\right.$ $\left.(\mu-\mathrm{H})_{4} \mathrm{H}(\mu-\mathrm{Cl})\right] \quad 2, \quad\left[\mathrm{Os}_{8} \mathrm{Pd}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{4}(\mu-\mathrm{Cl})_{2}\right] \quad$ 3. $\quad\left[\left\{\mathrm{O}_{3} \mathrm{Pd}(\mathrm{CO})_{s}(\mu-\mathrm{H})_{2}(\mu-\mathrm{Cl})\right\}_{2}(\mu-\mathrm{Cl})_{2}\right] \quad 4$, $\left[\mathrm{Os}_{4} \mathrm{Pd}(\mathrm{CO})_{11}(\mu-\mathrm{H})_{3}(\mu-\mathrm{Cl})_{3}(\mathrm{py})\right] 5$ and three known osmium clusters, $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{OH})\right]$. $\left.\left[\mathrm{Os}_{3}{ }^{4} \mathrm{CO}\right)_{10}(\mu-\mathrm{H})(\mu-\mathrm{Cl})\right]$ and $\left[\mathrm{Os}_{4}(\mathrm{CO})_{13}(\mu-\mathrm{H})_{2}\right]$. All five mixed-metal clusters were characterized by IR. 'H NMR and mass spectroscopy and X-ray crystallography. Complexes 1-3 have similar metal dispositions but different combinations of bridging hydrides and chlorides. They can be viewed as a diosmium fragment connected to the palladium vertex of the $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedron through a number of bridging ligands. Complex 4 is dimeric with two $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedra tied together by two bridging chlorides in a planar fashion. Complex 5 consists of an $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedron with a fourth osmium atom linked to the palladium vertex by three bridging chlorides. The pyridine ligand is co-ordinated to the singular osmium instead of the palladium atom.

In 1990 Adams et al. ${ }^{1}$ reported the hydrogenation reaction of [ $\mathrm{Os}_{4} \mathrm{Pt}_{2}(\mathrm{CO})_{18}$ ] to give a series of hydrido complexes, one of which was $\left[\mathrm{Os}_{5} \mathrm{Pt}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right.$ ]. The role of these complexes as hydrogen storage materials and the rich reactivities of the large number of osmium-platinum carbonyl clusters synthesized ${ }^{1-3}$ has aroused our interest in the synthesis and chemistry of osmium-palladium complexes. We have recently reported the syntheses of two Os-Pd clusters, namely $\left[\mathrm{Os}_{6} \mathrm{Pd}(\mathrm{CO})_{18} \text { (bipy) }\right]^{4}$ (bipy $=2,2^{\prime}$-bipyridine) and $\left[\mathrm{Os}_{3}\{\mathrm{Pd}-\right.$ (bipy) $\left.\}_{2}(\mathrm{CO})_{12}\right],{ }^{5}$ obtained from the complex $[\mathrm{Pd}($ bipy $)-$ $\left.\left(\mathrm{CO}_{2} \mathrm{Me}\right)_{2}\right]$ and activated triosmium clusters. We believe that the presence of a nitrogen-donor ligand stabilizes the mixedmetal clusters, as compared to the intractable intermediates obtained in the coupling reaction of $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mathrm{NCMe})_{2}\right]$ with palladium(n) salts. ${ }^{6}$ Herein, we report the direct synthesis of the palladium analogue of $\left[\mathrm{Os}_{5} \mathrm{Pt}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right]$ and a number of hydrido mixed-metal complexes by the reaction of $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right]$ and $\operatorname{trans}-\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right]$ ( $\mathrm{py}=$ pyridine ).

## Results and Discussion

On treatment of $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right]$ with trans $-\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right]$ a series of clusters with a common tetrahedral $\mathrm{Os}_{3} \mathrm{Pd}$ unit was formed including the new complexes $\left[\mathrm{Os}_{5} \mathrm{Pd}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right]$ 1, $\left[\mathrm{Os}_{5} \mathrm{Pd}(\mathrm{CO})_{16}\left(\mu-\mathrm{H}_{4}\right) \mathrm{H}(\mu-\mathrm{Cl})\right]$ 2, $\left[\mathrm{Os}_{5} \mathrm{Pd}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{4}(\mu-\mathrm{Cl})_{2}\right]$ 3, $\left[\left\{\mathrm{Os}_{3} \mathrm{Pd}(\mathrm{CO})_{9}(\mu-\mathrm{H})_{2}(\mu-\mathrm{Cl})\right\}_{2}(\mu-\mathrm{Cl})_{2}\right] \quad 4$ and $\left[\mathrm{Os}_{4} \mathrm{Pd}-\right.$ $\left.(\mathrm{CO})_{11}(\mu-\mathrm{H})_{3}(\mu-\mathrm{Cl})_{3}(\mathrm{py})\right] 5$ and the known clusters $\left[\mathrm{Os}_{3}-\right.$ $\left.(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{OH})\right],\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{Cl})\right]$ and $\left[\mathrm{Os}_{4}{ }^{-}\right.$ $(\mathrm{CO})_{13}(\mu-\mathrm{H})_{2}$ ]. Similar basic units had been obtained from reactions of the unsaturated hydridoosmium cluster with complexes of nickel, ${ }^{7}$ platinum ${ }^{8,9}$ and iridium. ${ }^{10}$ A mechanism had been proposed by Stone and co-workers ${ }^{9}$ for the formation of $\left[\mathrm{Os}_{3} \mathrm{Pt}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)_{3}\right\}\right]$. In the trans$\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right]$ reaction the formation of the clusters is believed

[^0]to proceed through chloride-bridged intermediates, as revealed by the presence of chloride groups in four of the five new compounds. The only compound that contains pyridine as ligand is complex 5 , where it is co-ordinated to an osmium atom. This evidences the substitution lability of monodentate pyridine as compared to bidentate bipyridine, the latter being bound to the palladium in both $\left[\mathrm{Os}_{6} \mathrm{Pd}(\mathrm{CO})_{18}(\text { bipy })\right]^{4}$ and $\left[\mathrm{Os}_{3}\{\mathrm{Pd}(\text { bipy })\}_{2}(\mathrm{CO})_{12}\right]$. ${ }^{5}$ Similar ligand transfer has been observed in $\left[\mathrm{NiOs}_{3}(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{8}(\mu-\mathrm{H})_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right]^{7}$ and $\left[\mathrm{Os}_{3} \mathrm{Pt}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right]{ }^{2}$ The presence of the $\mathrm{Os}_{2}$ units in complexes 1-3 suggests the detachment of a monoosmium fragment from $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right.$ ] in the course of reaction, which is trapped in 5 and $\left[\mathrm{Os}_{4}(\mathrm{CO})_{13}(\mu-\mathrm{H})_{2}\right]$. The formation of $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{Cl})\right]$ is probably the direct outcome of the rearrangement of the intermediate species. The presence of residual moisture from the synthesis of the palladium reactant accounts for the formation of $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{OH})\right]$. The three known osmium clusters are characterized by IR and ${ }^{1} \mathrm{H}$ NMR spectroscopy. ${ }^{11,12}$

Spectroscopic Data for Complexes 1-5.-A summary of the spectroscopic data for complexes $1-5$ is given in Table 1. Only terminal carbonyls were observed in the IR region ( $v_{\mathrm{co}} 2200-$ $1600 \mathrm{~cm}^{-1}$ ) for solutions of the complexes. The presence of hydrides in all the complexes was confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy. For 1 three different metal hydride signals were observed with a total integral of 6 . All three signals are singlets due to internal rotation of the metal fragments. ${ }^{1 b}$ The upfield signal at around $\delta-16$ (which also occurs for the other four complexes) is attributed to the three hydrides bridging the $\mathrm{Os}-\mathrm{Os}$ bonds of the $\mathrm{Os}_{3} \mathrm{Pd}$ unit. The other signals are assigned to hydrides bridging the $\mathrm{Os}-\mathrm{Pd}$ bonds of the triangular fragment. The more downfield signal is attributed to the double hydride bridge across a single bond which is electron deficient in nature. A similar situation occurs in the platinum analogue $\left[\mathrm{Os}_{5} \mathrm{Pt}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right]$ which exhibits resonances at $\delta-7.48$, -12.17 and $-17.36 .^{1}$ Complex 2 also reveals three hydride

resonances. As for 1, the upfield singlet originates from the bridging hydrides in the $\mathrm{Os}_{3}$ triangle. The signal due to the Os-Pd bridging hydride appears slightly downfield while the most downfield signal is ascribed to the terminal hydride on the osmium possessing four carbonyl ligands. A similar terminal hydride has been found in $\left[\mathrm{Os}_{4}(\mathrm{CO})_{15} \mathrm{H}_{2}\right]^{13}$ and $\left[\mathrm{Os}_{6}\right.$ $\left.(\mathrm{CO})_{19} \mathrm{H}_{2}\right]^{14}$ which give comparable signals at $\delta-9.6$ and -9.0 respectively.

Similarly the two signals of complex 3 are assigned to the hydride bridging the osmium and palladium atoms and those bridging the Os-Os bonds. From the electron count, complex 4 is expected to possess two hydrides on each monomer resulting in 60 cluster valence electrons (c.v.e.s) for each tetrahedral unit. These hydrides become chemically equivalent in solution as revealed by the singlet in the ${ }^{1} \mathrm{H}$ NMR spectrum. Thus, unlike $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{Cl})\right],{ }^{11}$ the $\mathrm{Os}-\mathrm{Os}$ bonds in the $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedra are all singly bridged by either hydride or chloride. Complex 5 is the only one to reveal an N -co-ordinated pyridine signal in the NMR spectrum. All the mass spectra reveal molecular-ion peaks conforming to the proposed formulae.

Crystal Structures of Complexes 1-5.-An ORTEP ${ }^{15}$ diagram of complex 1 is depicted in Fig. 1, and selected bond lengths and angles are given in Table 2. The metal skeleton of 1 consists of an $\mathrm{Os}_{2} \mathrm{Pd}$ triangle fused to an $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedron at the palladium apex. The mixed-metal triangle is almost perpendicular to the $\mathrm{Os}_{3}$ base of the tetrahedron, with a dihedral angle of $96.10^{\circ}$. Similar metal arrangements have been found in the platinum analogue $\left[\mathrm{Os}_{5} \mathrm{Pt}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right]^{1}$ and in $\left[\mathrm{Co}_{5} \mathrm{Ge}(\mathrm{CO})_{16}\right]^{-} .{ }^{16}$ The complex $\left[\mathrm{Os}_{5} \mathrm{Pt}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right]$ crystallizes in the centrosymmetric space group $P 2_{1} / n$ while 1 crystallizes in the acentric space group $\operatorname{Pna} 2_{1}$. The $\mathrm{Os}-\mathrm{Os}$ bond lengths range from $2.828(2)$ to $2.909(2) \AA\{c f .2 .877(3) \AA$ in $\left.\left[\mathrm{Os}_{3}(\mathrm{CO})_{12}\right]^{17}\right\}$. Each osmium atom has three terminal carbonyl ligands except for $\mathrm{Os}(5)$ which has four. The carbonyl ligands of $\mathrm{Os}(4)$ and $\mathrm{Os}(5)$ are arranged in a staggered manner to release steric constraints. The sides of the basal $\mathrm{Os}_{3}$ triangle

Fig. 1 Molecular structure of $\left[\mathrm{Os}_{5} \operatorname{Pd}(\mathrm{CO})_{16}(\mu-\mathrm{H})_{6}\right] 1$
are all bridged by hydrides. Three kinds of $\mathrm{Os}-\mathrm{Pd}$ bonds are observed in the compound: unsupported [ $\mathrm{Os}(1)-\mathrm{Pd}, \mathrm{Os}(2)-\mathrm{Pd}$ and $\mathrm{Os}(3)-\mathrm{Pd}]$, singly hydride-bridged [ $\mathrm{Os}(5)-\mathrm{Pd}]$ and doubly hydride-bridged [ $\mathrm{Os}(4)-\mathrm{Pd}$ ]. The unsupported ones comprise the shortest members of the group, which are even shorter than those found in $\left[\mathrm{Os}_{6} \mathrm{Pd}(\mathrm{CO})_{18}\right.$ (bipy)]. ${ }^{4}$ On the other hand, $\mathrm{Os}(5)-\mathrm{Pd}$ is the longest and is accounted for by both steric and electronic factors. The cluster has 88 c.v.e.s, which is two short according to electron-counting rules. As mentioned by Adams et al., ${ }^{1}$ such electron deficiency accounts for the comparatively short $\mathrm{Os}(4)-\mathrm{Pd}$ bond despite the existence of the two bridging hydrides.

The crystal structure of complex 2 is shown in Fig. 2, with a summary of the bond lengths and angles in Table 3. The metal disposition is similar to that of complex 1, except that no formal $\mathrm{Os}-\mathrm{Pd}$ bond is expected between $\mathrm{Os}(5)$ and the palladium atom [Os(5) $\cdots$ Pd $3.10 \AA$ ] from the electron count (see below). A total of four mixed-metal bonds are found, of which three are unsupported. The fourth is doubly bridged by a hydride and a chloride as in $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{Cl})\right],{ }^{11}$ and is slightly longer than the others $[2.870(2) \AA$, cf. average $2.677 \AA$ for the
unsupported ones]. The four atoms $\mathrm{Os}(4), \mathrm{Cl}, \mathrm{Pd}$ and $\mathrm{H}(1)$ lie on a plane, with the ligands bridging on the opposite sides of the $\mathrm{Os}-\mathrm{Pd}$ bond. Atom $\mathrm{Os}(5)$ is the only six-co-ordinated osmium, possessing a terminal hydride and four carbonyl ligands in addition to the $\mathrm{Os}-\mathrm{Os}$ bonding. Such a terminal hydride is a common feature in the 'spiked' atom configuration as in $\left[\mathrm{Os}_{4}(\mathrm{CO})_{15} \mathrm{H}_{2}\right]^{13}$ and $\left[\mathrm{Os}_{6}(\mathrm{CO})_{19} \mathrm{H}_{2}\right.$..$^{14}$ The remaining hydrides bridge the $\mathrm{Os}-\mathrm{Os}$ bonds of the $\mathrm{Os}_{3}$ face. All the carbonyl ligands are terminal. As in complex 1, those on Os(4) and $\mathrm{Os}(5)$ take up a staggered conformation.
An ORTEP view of complex 3 is depicted in Fig. 3 and selected bonding parameters in Table 4. Unlike 1 and $\mathbf{2}$, the $\mathbf{O s}_{2}$

fragment in complex 3 is connected to the $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedron through the hydride and chloride ligands only. The two chloride ligands bridge $\mathrm{Os}(4)$ and Pd with no formal bonding assigned between the metal atoms $\left\{c f .\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{Cl})_{2}\right]^{18}\right\}$ while the hydride connects $\mathrm{Os}(5)$ to Pd . The seven carbonyl groups are staggered in the $\mathrm{Os}_{2}$ unit. All the $\mathrm{Os}-\mathrm{Os}$ bonds are bridged by hydride ligands in the tetrahedron, with three terminal carbonyls on each osmium atom.
The bonding situation of complexes 1-3 illustrates the effect of additional electron pairs on a cluster complex as implied by the effective atomic number (e.a.n.) rule or from the classical view of metal-metal bonding (see Scheme 1). The complexes have 88,90 and 92 c.v.e.s respectively, with the electron pair

${ }^{1}=$
c.v.e. $=88$

Scheme 1
added through the substitution of hydride ligands by bridging chlorides. The addition of an extra electron pair results in the rupture of a metal-metal bond, as observed from the subsequent reduction in the number of metal-metal bonds in the complexes. None of the structures is electron precise. They can neither be predicted by the polyhedral skeletal electron-pair theory (PSEPT) ${ }^{19}$ nor be rationalized by the condensed polyhedral electron-counting rule. ${ }^{20}$

The bond lengths and angles of complex 4 are summarized in Table 5. Complex 4 is dimeric as shown in the ORTEP plot in Fig. 4. Dimeric clusters are not uncommon and various sorts of linkage of the metal cages have been observed: atomic bridge, ${ }^{21,22}$ molecular bridge ${ }^{23,24}$ or direct linkage by metalmetal bonding of the apical atoms. ${ }^{25,26}$ The asymmetric unit comprises the monomer and a water molecule, with the whole molecule generated by crystallographic inversion symmetry. The two $\mathrm{Os}_{3} \mathrm{Pd}$ tetrahedra are connected via two chloride bridges $\left[\mathrm{Pd}(1)-\mathrm{Cl}(1) 2.495(6)\right.$ and $\left.\mathrm{Pd}(1)-\mathrm{Cl}\left(1^{*}\right) 2.432(6) \AA\right]$. A central $\mathrm{Pd}_{2} \mathrm{Cl}_{2}$ unit is a commonly observed structural component in chloroorganopalladium dimeric complexes. ${ }^{27-29}$ A similar dibromo-bridge is also observed in $\left[(\mathrm{HgBr})_{2}\left\{\mathrm{Pt}_{3}(\mu-\right.\right.$ $\left.\left.\mathrm{CO})_{3}\left[\mathrm{PPh}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)_{2}\right]_{3}\right\}_{2}(\mu-\mathrm{HgBr})_{2}\right] .{ }^{22} \mathrm{~A}$ second chloride ligand is found to bridge an $\mathrm{Os}-\mathrm{Os}$ bond in the asymmetric unit. Two hydride ligands (see above) bridge the remaining $\mathrm{Os}-\mathrm{Os}$ bonds. An incipient bridging carbonyl ligand occurs, which asymmetrically bridges $\mathrm{Os}(1)-\mathrm{Pd}(1)$ [ $\mathrm{Os}(1)-\mathrm{C}(1)-\mathrm{O}(1) \mathrm{170(2)}$, $\left.\mathrm{Pd}(1)-\mathrm{C}(1)-\mathrm{O}(1) 112(1)^{\circ}\right]$. It is probably imposed by the packing forces in the lattice and may not occur in the solution state. The rest of the carbonyl ligands are all terminal. The fragments $\mathrm{Pd}(1)-\mathrm{Os}(2)-\mathrm{Cl}(2)-\mathrm{Os}(1)$ and $\mathrm{Cl}(1)-\mathrm{Pd}(1)-$ $\mathrm{Os}(3)-\mathrm{Os}(2)$ are almost planar, with maximum deviations of 0.065 and $0.070 \AA$ respectively. The $\mathrm{OsPdCl}_{2}$ plane is perpendicular to the $\mathrm{Os}_{2} \mathrm{PdCl}$ and $\mathrm{Os}_{3}$ planes. Each tetrahedral unit possesses 60 c.v.e.s, giving a total of 120 to the entire

molecule. This is not expected from the PSEPT rule but obeys the e.a.n. rule.

Complex 5 is the only pyridine-containing product from the reaction, as confirmed by both spectroscopic and structural analyses. An ORTEP plot (Fig. 5) reveals a basic $\mathrm{Os}_{3} \mathrm{Pd}$ unit with the fourth osmium 'clamped' to the palladium by three bridging chlorides. Despite the identity of the palladium reagent, the pyridine ligand is co-ordinated to the $\mathrm{Os}(\mathrm{CO})_{2}$ fragment. Each $\mathrm{Os}-\mathrm{Os}$ bond is bridged by a hydride ligand as in compounds 1-3. All the carbonyl ligands are terminal and the bonding parameters (Table 6) of the pyridine ligand are similar to those observed in other pyridine-containing complexes. In addition to the cluster molecule, the crystal lattice contains a badly disordered hexane solvent molecule. The cluster possesses 78 c.v.e.s consistent with the e.a.n. rule.

## Experimental

Materials and Methods.-The reaction was performed in an atmosphere of dry dinitrogen. Dichloromethane and aceto-

nitrile were distilled over calcium hydride. Diethyl ether was dried over sodiun wire. Acetone (GR) was stored over $4 \AA$ molecular sieves prior to use. All chemicals were obtained from commercial sources. The complex $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right]$ was prepared by the literature method. ${ }^{30}$ Infrared spectra were recorded on a Bio-Rad FTS-7 IR spectrometer, using 0.5 mm calcium fluoride solution cells, NMR spectra on a JEOL GSX 270FT-NMR spectrometer with $\mathrm{SiMe}_{4}$ as internal reference and mass spectra on a Finnigan MAT 95 instrument by the fast atom bombardment technique. Products were separated by thin-layer chromatography on plates coated with Merck Kieselgel 60 GF $_{254}$.

Synthesis of trans- $\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right]$.-The complex was prepared by an improved synthesis of the analogous compound [ Pd (bipy) $\left.\mathrm{Cl}_{2}\right] \cdot{ }^{31}$ Palladium(II) chloride ( $0.1 \mathrm{~g}, 0.56 \mathrm{mmol}$ ) was dissolved in boiling acetonitrile ( $30 \mathrm{~cm}^{3}$ ). After filtration a fivefold excess of pyridine ( $0.25 \mathrm{~cm}^{3}, 3.09 \mathrm{mmol}$ ) was added to the boiling solution. Bright yellow needles gradually formed on stirring. The volume of the solution was reduced to $20 \mathrm{~cm}^{3}$, and then digested for 4 h . The precipitate was filtered off and washed with acetonitrile ( $2 \times 3 \mathrm{~cm}^{3}$ ), acetone ( $2 \times 3 \mathrm{~cm}^{3}$ ) and diethyl ether ( $3 \mathrm{~cm}^{3}$ ). The product was dried in vacuo and its geometry confirmed by IR spectroscopy. ${ }^{32}$ Yield: 0.16 g ( $87 \%$ ).

Reaction of trans- $\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right]$ with $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right]$.The complex $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})_{2}\right](34 \mathrm{mg}, 0.040 \mathrm{mmol})$ was treated with trans- $\left[\mathrm{Pd}(\mathrm{py})_{2} \mathrm{Cl}_{2}\right](20 \mathrm{mg}, 0.060 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $20 \mathrm{~cm}^{3}$ ) at room temperature. The mixture was stirred for 2 h prior to reduction in volume. The products were separated by TLC on silica, with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$-hexane ( $1: 7, \mathrm{v} / \mathrm{v}$ ) as eluent, as six bands. The first yellow band was a mixture, which was subjected to TLC again using pure hexane as eluent to afford $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{OH})\right](4 \mathrm{mg}, 0.0046 \mathrm{mmol}, 11 \%)$ and $\left[\mathrm{Os}_{3}(\mathrm{CO})_{10}(\mu-\mathrm{H})(\mu-\mathrm{Cl})\right](7 \mathrm{mg}, 0.0079 \mathrm{mmol}, 20 \%)$. An orange compound ( $R_{\mathrm{f}} 0.50$ ) was then eluted and confirmed by IR and NMR spectroscopy to be $\left[\mathrm{Os}_{4}(\mathrm{CO})_{13}(\mu-\mathrm{H})_{2}\right](4 \mathrm{mg}, 0.0035$ $\mathrm{mmol}, 9 \%$ ). Three consecutive bands were then eluted, namely complex 1 ( $R_{\mathrm{f}} 0.36 ; 8 \mathrm{mg}, 0.0053 \mathrm{mmol}, 13 \%$ ), $2\left(R_{\mathrm{f}} 0.31 ; 7 \mathrm{mg}\right.$, $0.0045 \mathrm{mmol}, 11 \%$ ) and 3 ( $R_{\mathrm{f}} 0.25 ; 4 \mathrm{mg}, 0.0025 \mathrm{mmol}, 6 \%$ ). The red baseline portion was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and subjected to fractional crystallization to give pure $4(10 \mathrm{mg}, 0.0050 \mathrm{mmol}$, $12.5 \%$ ) and then $5(4 \mathrm{mg}, 0.0029 \mathrm{mmol}, 7 \%)$.
$X$-Ray Data Collection and Structural Determination of Complexes 1-5.-All pertinent crystallographic data and other experimental details are summarized in Table 7. Data were collected at ambient temperature on a Rigaku AFC7R
diffractometer, using Mo-K $\alpha$ radiation $(\lambda=0.71073 \AA$ ) with a graphite-crystal monochromator in the incident beam. The unit-cell parameters were determined from 25 accurately centred reflections. All the data were collected at room temperature ( 298 K ) using the $\omega-2 \theta$ scan technique with a scan rate of $16.0^{\circ} \mathrm{min}^{-1}$ (in $\omega$ ). The weak reflections were rescanned (up to four scans) and the counts were accumulated. The stability of the crystals was monitored at regular intervals using three standard reflections and no significant decay was observed. The diffracted intensities were corrected for Lorentz and polarization effects. The $\psi$-scan method was employed for semiempirical absorption corrections. ${ }^{33}$ Scattering factors were taken from ref. 34(a) and anomalous dispersion effects ${ }^{34 b}$ were included in $F_{\mathrm{c}}$.

The structures were solved by direct methods ${ }^{35}$ and expanded by Fourier techniques. The solutions were refined on $F$ by full-matrix least-squares analysis with $\mathrm{Os}, \mathrm{Pd}$ and Cl atoms refined anisotropically. The hydrogen atoms of the pyridine ligand in complex 5 were generated in their ideal positions ( $\mathrm{C}-\mathrm{H} 0.95 \AA$ ). The hydrogen atoms of the water molecule in 4 , the terminal (2) and the Os-Pd bridging hydrides (1-3) were located on the Fourier-difference map of the low-angle data, whilst the Os-Os bridging hydrides for all the complexes were

located by potential-energy calculations. ${ }^{36}$ All the hydrogen atoms were included in the structure factors but the parameters were fixed without further refinement. Owing to the disorder of the hexane molecule in complex 5 , no hydrogen atoms were introduced. The carbon atoms were fixed as obtained but included in the structure factor for subsequent refinement of the structure. Calculations were performed on a Silicon-Graphics computer, using the program package TEXSAN. ${ }^{37}$ Positional parameters for the non-hydrogen atoms of the complexes are given in Tables 8-12.
Additional material available from the Cambridge Crystallographic Data Centre comprises H -atom coordinates, thermal parameters and remaining bond lengths and angles.
