ALTO

Pyrazin-2-yl 2-pyridyl sulfide (pzpys) has been prepared by reaction of 2-sulfanylpyridine with chloropyrazine. As shown by ¹H NMR spectroscopy, its major isomer has two binding sites which are inequivalent, one chelating through the N¹-pyrazine and N-pyridine atoms, the other monodentate through the N⁴ atom of the pyrazine ring. By reaction of pzpys with $[RuL_2(NO)(NO_2)][PF_6]_2 [(L = 2,2'-bipyridine (bipy) or di-2-pyridyl$ sulfide (dps)] the mononuclear complexes $[RuL_2(pzpys)(NO_2)][PF_6]$ have been obtained in which pzpys is the monodentate. The reactions of pzpys with cis-[RuL₂Cl₂] complexes [L = bipy, 1,10-phenanthroline (phen) or dps] have been studied. The dps derivative reacts with a large excess of pzpys affording [Ru(dps)₂(pzpys)Cl]- $[PF_6]$ in which pzpys is monodentate. On the contrary the bipy and phen (L) derivatives, under the same experimental conditions, undergo substitution of both chloride ligands giving, as major products, $[RuL_2(pzpys)][PF_6]_2$ in which pzpys is chelated. When the reactions were carried out in the presence of a stoichiometric amount of pzpys the binuclear complexes $[L_2Ru(pzpys)RuL_2Cl][PF_6]_3$ (L = bipy or phen) were slowly formed. The mononuclear complexes have been used as ligands in the reactions with [Ru- $(bipy)_2Cl_2$ giving the new binuclear species $[L_2Ru(pzpys)RuL_2(NO_2)][PF_6]_3$ (L = bipy or phen). The compounds have been fully characterized by infrared, UV/VIS, ¹H and ¹³C NMR spectroscopies. In acetonitrile solution $[Ru(bipy)_2(pzpys)Cl][PF_6]$ undergoes a reversible $Ru^{II} \longrightarrow Ru^{III}$ electron transfer. In contrast, the one-electron oxidation of [Ru(dps)₂(pzpys)Cl][PF₆], [Ru(bipy)₂(pzpys)(NO₂)][PF₆] and $[Ru(bipy)_2(pzpys)][PF_6]_2$ is complicated by subsequent chemical reactions. The binuclear complex $[(bipy)_2 Ru(pzpys)Ru(bipy)_2 Cl][PF_6]_3$ undergoes two consecutive one-electron oxidations ($\Delta E^{\circ \prime} = 0.55$ V), which allow the corresponding Ru^{II}Ru^{III} species to be classified as a completely delocalized (Class III) mixedvalence compound.

Binuclear polypyridylruthenium(II) complexes in which the metals are linked by the appropriate N-donor bridging ligands have attracted much attention due to their ability to generate mixed-valence complexes of fundamental interest in the electron-transfer field.¹⁻⁵ The construction of homo- and hetero- bi- and poly-nuclear polypyridylruthenium complexes is also of interest in the photochemical and photophysical area because suitable bridging ligands allow electronic communication between the Ru(bipy)₃ (bipy = 2,2'-bipyridine) or similar 'antenna' group and the reaction centre.^{5,6}

Despite the large body of work devoted to the synthesis and characterization of complexes of the general type $[L_2XRu(L-L)RuXL_2]^{2+}$ or $[L_2Ru(L-L)RuL_2]^{4+}$ (L = bipy or bipy-like ligand, X = Cl or NO₂), containing exobidentate bridging ligands¹⁻³ such as pyrazine, 4,4'-bipyridine or bis(chelating) ligands^{4.6} such as 2,3-bis(2-pyridyl)pyrazine, 2,2'-bipyrimidine, 'back to back' bis(bipyridine) and bis(terpyridine), examples of binuclear complexes containing terdentate binucleating ligands are much rarer.³⁴ Moreover the preparation of new binuclear complexes requires, as a first step, the design and synthesis of binucleating compounds^{6.7} followed by a direct synthesis of the binuclear species or by a stepwise method through the synthesis of mononuclear complexes able to act as ligands.^{6,8,9a}

Following our interest in the chemistry of the bipyridine-like ligands⁹ we report in this paper the preparation and characterization of the new compound pzpys which may act as mono- or bi-dentate mononucleating and exobidentate or terdentate binucleating ligand. The use of this polyfunctional

compound allows the synthesis of mononuclear complexes which can act as monodentate or chelating ligands depending on the attachment mode of pzpys, as well as the one-step synthesis of asymmetric binuclear species containing RuL₂Cl and RuL₂ units. The control of the co-ordination mode of the ligand may be achieved by opportune choice of the starting complex. The complexes [RuL₂Cl₂] [L = bipy^{4a.6.7b,8a.b} or 1,10-phenanthroline (phen)^{8a.c}] and [Ru(terpy)Cl₃]^{6.8d} (terpy = 2,2':6',2"-terpyridine) are expected to favour the chelation of pzpys by substitution of both chloride ligands, while nitrosyl derivatives [RuL₂(NO)X][PF₆]₂^{2.3b.c.10} or complexes such as [RuA₂Cl₂] (A = di-2-pyridyl ketone,¹¹ di-2-pyridyl sulfide^{9a} or sterically hindering diimines¹²) are expected to give species in which pzpys is monodentate.

We also report the synthesis and NMR characterization of a series of mono- and bi-nuclear ruthenium(II) complexes containing pzpys as mono- or bi-dentate mononucleating and terdentate binucleating ligand, respectively.

Experimental

[†] Non-SI unit employed: mmHg \approx 133 Pa.

published methods. Elemental analyses were carried out by Redox Microanalytical Laboratory of Cologno Monzese (Milano). Conductivity measurements were done on a Radiometer CDM 3 conductivity meter. Infrared spectra were recorded on an FT-IR 1720X spectrophotometer with samples as Nujol mulls placed between CsI plates, electronic absorption spectra on a Perkin-Elmer Lambda 5 spectrophotometer and the ¹H and ¹³C NMR spectra on a Bruker AMX 300 spectrometer. Materials and apparatus for electrochemistry were described elsewhere.¹⁶ Potentials are referred to the saturated calomel electrode (SCE). All the syntheses were performed under N2, and the synthesis and work-up of the binuclear complexes also required protection from light. Crystallization was performed by dissolving the products in acetone and filtering into an excess of stirred diethyl ether. All the complexes obtained were washed with diethyl ether and dried over P_4O_{10} in vacuo.

Preparations

Pyrazin-2-yl 2-pyridyl sulfide. The compounds 2-sulfanylpyridine (11.3 g, 0.1 mol), chloropyrazine (11.4 g, 0.1 mol) and potassium carbonate (15 g, 0.1 mol) were vigorously stirred in dimethylformamide (30 cm³) and refluxed for 4 h. The dimethylformamide was then distilled under reduced pressure (100 mmHg) and the residue distilled at 7 mmHg (b.p. 140 °C). The yellow oil obtained was kept at 4 °C to give a waxy solid. Yield 11.4 g (60%) (Found: C, 57.15; H, 3.75; N, 22.20; S, 16.90. C₉H₇N₃S requires C, 57.10; H, 3.75; N, 22.20; S, 16.95%). IR: 3046s, 1605s, 1574vs, 1562s, 1510s, 1451vs, 1419vs, 1387s, 1288s, 1144vs, 1116vs, 1086s, 1047s, 1010s, 988s, 841s, 765vs, 738s, 722vs and 401s cm⁻¹.

[Ru(bipy)₂(pzpys)Cl][PF₆]·H₂O 1. The complex [Ru(bipy)₂-Cl₂]·2H₂O (0.520 g, 1 mmol) and AgPF₆ (0.253 g, 1 mmol) were dissolved in acetone (30 cm³) and stirred for 4 h in the dark. The compound pzpys (0.946 g, 5.0 mmol) was then added and the suspension stirred for 2 h. Silver chloride was filtered off and the resulting solution concentrated (10 cm³) and added to diethyl ether (100 cm^3) . The precipitate obtained was washed with diethyl ether, dissolved in acetone (ca. 10 cm^3) and added to the top of a chromatography column (diameter 2 cm) packed with aluminium oxide (80 g; Aldrich, neutral, STD grade, 150 mesh) deactivated with water (6 g). Elution with acetonetoluene (3:2) gave a red band which was collected, concentrated (10 cm³) and treated with diethyl ether. The red solid obtained was crystallized. Yield: 0.32 g (40%) (Found: C, 43.40; H, 3.15; N, 12.15; S 3.90. C₂₉H₂₅ClF₆N₇OPRuS requires C, 43.50; H, 3.15; N, 12.25; S, 4.00%). IR: 1605s, 1569s, 1160s, 844 (br), 765vs, 731s, 759vs and 338ms cm $^{-1}$. $\Lambda_{M}(MeCN,\,2\,\times\,10^{-4}$ mol dm^{-3} , 20 °C) = 180 Ω^{-1} cm² mol⁻¹.

From a second orange band, as described for complex 6, $[Ru(bipy)_2(pzpys)][PF_6]_2$ (*ca.* 30%) was obtained.

[**Ru(dps)₂(pzpys)Cl]**[**PF**₆]·**H**₂**O 2.** This complex was obtained as described for 1 starting from [Ru(dps)₂Cl₂]·2H₂O (0.293 g, 0.5 mmol), AgPF₆ (0.126 g, 0.5 mmol) and pzpys (0.757, 4 mmol). Yield *ca.* 40% (Found: C, 40.30; H, 3.00; N, 11.30; S, 11.15. C₂₉H₂₅ClF₆N₇OPRuS₃ requires C, 40.25; H, 2.90; N, 11.35; S, 11.10%). IR: 1586s, 1569s, 1164s, 845 (br), 768vs, 741ms, 559vs and 335ms cm⁻¹. Λ_M(MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 170 Ω⁻¹ cm² mol⁻¹.

[Ru(bipy)₂(pzpys)(NO₂)][PF₆]·H₂O 3 and [Ru(dps)₂(pzpys)-(NO₂)][PF₆]·H₂O 4. Potassium azide (0.08 g, 1 mmol) was dissolved in warm methanol (10 cm³) and added dropwise to a stirred solution of [Ru(bipy)₂(NO)(NO₂)][PF₆]₂ (0.78 g, 1 mmol) or [Ru(dps)₂(NO)(NO₂)][PF₆]₂·H₂O (0.861 g, 1 mmol), in acetone (15 cm³). The dark red solution obtained was stirred for 20 min. An acetone solution (5 cm³) of pzpys (0.95 g, 5.0 mmol) was then added. The solution was stirred for 3 h, filtered and added to diethyl ether (150 cm³). The orange 3 or yellow 4 solid obtained was filtered off, washed copiously with diethyl ether and crystallized. Yield *ca.* 70% for both compounds. Complex 3 (Found: C, 42.80; H, 3.10; N, 13.70; S 4.00. $C_{29}H_{25}F_6N_8O_3PRuS$ requires C, 42.90; H, 3.10; N, 13.80; S, 3.95%); IR 1605s, 1572vs, 1339vs, 1297vs, 1162s, 1116s, 843 (br), 767vs, 732s and 559vs cm⁻¹; Λ_M (MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 180 Ω^{-1} cm² mol⁻¹. Complex 4 (Found: C, 39.70; H, 2.95; N, 12.70; S 11.00. $C_{29}H_{25}F_6N_8O_3PRuS_3$ requires C, 39.75; H, 2.90; N, 12.80; S, 11.00%); IR 1629s, 1589vs, 1342vs, 1297vs, 1165s, 1116s, 844 (br), 770vs, 741ms, 726s and 559vs cm⁻¹; Λ_M (MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 160 Ω^{-1} cm² mol⁻¹.

Complexes 1 and 2 were obtained in the same way starting from $[Ru(bipy)_2(NO)Cl][PF_6]_2$ (0.769 g, 1 mmol) or $[Ru(dps)_2(NO)Cl][PF_6]_2$ (0.833 g, 1 mmol), respectively, potassium azide (0.08 g, 1 mmol) and pzpys (0.946 g, 5.0 mmol). Yields *ca.* 30 (1) and *ca.* 40% (2).

[Ru(bipy)₂(pzpys)(NO)][PF₆]₃·H₂O 5. To a stirred methanol solution (25 cm³) of the complex [Ru(bipy)₂(pzpys)(NO₂)]-[PF₆]·H₂O (0.203 g, 0.25 mmol) was slowly added a 70% aqueous solution of HPF₆ (1 cm³). The reaction mixture was stirred for 1 h, then water (10 cm³) was added and the solid complex 5 obtained filtered off, washed with water (30 cm³), methanol-water (10 cm³, 1:1) and diethyl ether (30 cm³). Yield: *ca.* 60%. (Found: C, 32.10; H, 2.40; N, 10.25; S 3.00. C₂₉H₂₅F₁₈N₈O₂P₃RuS requires C, 32.10; H, 2.30; N, 10.30; S, 2.95%). IR: 1947vs, 1609s, 1573ms, 1506s, 1324s, 1294s, 839 (br), 767vs, 741ms, 726s and 559vs cm⁻¹. Λ_M(MeCN, $2 \times 10^{-4} \text{ mol dm}^{-3}$, 20 °C) = 425 Ω⁻¹ cm² mol⁻¹.

 $[Ru(bipy)_2(pzpys)][PF_6]_2$ 6. The complex $[Ru(bipy)_2-$ Cl₂]·2H₂O (0.520 g, 1 mmol) and pzpys (0.946 g, 5 mmol) were refluxed in ethanol-water (2:1, 30 cm³) for 2 h, then stirred at room temperature for 2 d. The brown solution obtained was filtered and added to a stirred aqueous solution (100 cm^3) of NH₄PF₆ (1.63 g, 10 mmol). The crude product was collected, washed copiously with cold water, dried overnight and purified by chromatography. The preparation of the column and the elution of 1, as a red band, was performed as for 1 (yield ca. 10%). Elution with acetone-acetonitrile (4:1) gave an orange band which was concentrated (10 cm³) and precipitated with diethyl ether (100 cm³). The final yield of 6was 0.536 g (60%) (Found: C, 39.10; H, 2.60; N, 11.00; S, 3.60. C₂₉H₂₃F₁₂N₇P₂RuS requires C, 39.00; H, 2.60; N, 11.00; S, 3.60). IR: 1605s, 1567s, 1162s, 844 (br), 765vs, 732s and 559vs cm⁻¹. Λ_{M} (MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 305 Ω^{-1} cm² mol^{-1} .

[**Ru(phen)**₂(pzpys)][PF₆]₂ 7. This complex was obtained in the same way starting from [Ru(phen)₂Cl₂] (0.266 g, 0.5 mmol) and pzpys (0.474 g, 2.5 mmol). The crude product was purified by chromatography using acetone as eluent. The yield was 0.282 g (60%) (Found: C, 42.30; H, 2.50; N, 10.40; S, 3.40. C₃₃H₂₃F₁₂N₇P₂RuS requires C, 42.15; H 2.45; N, 10.40; S, 3.40%). IR: 1632s, 1568s, 1150s, 850 (br), 772vs, 724s and 559vs cm⁻¹. $\Lambda_{\rm M}$ (MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 310 Ω⁻¹ cm² mol⁻¹.

[(bipy)₂Ru(pzpys)Ru(bipy)₂Cl][PF₆]₃·2H₂O 8 and [(phen)₂-Ru(pzpys)Ru(phen)₂Cl][PF₆]₃·2H₂O 9. Although these complexes can be obtained as described for 10 starting from 6 and [Ru(bipy)₂Cl₂] or 7 and [Ru(phen)₂Cl₂], respectively, they were prepared more easily and in higher yields directly by reaction of [Ru(bipy)₂Cl₂] or [Ru(phen)₂Cl₂] (1 mmol) and pzpys (0.104 g, 0.55 mmol) in ethanol-water (2:1, 30 cm³) for 3 d. The reaction mixture was added to an aqueous solution (100 cm³) of NH₄PF₆ (1.63 g, 10 mmol). The dark red solid formed was filtered off, washed copiously with cold water and dried overnight. The crude product was dissolved in acetone and added to the top of a 15×2 cm diameter chromatography column (Aldrich, aluminium oxide, neutral, STD grade, 150 mesh deactivated with 11% water). The first orange band of 6 or 7 was eluted with acetone-toluene (3:1) (yield ca. 20%). Elution with acetone-acetonitrile (2:1) gave a purple band which was concentrated (10 cm³) and precipitated with diethyl ether (100 cm³). Yield ca. 55 (8) and 35% (9). Complex 8 (Found: C, 38.55; H, 2.90; N, 10.00; S, 2.00. C₄₉H₄₃ClF₁₈N₁₁-O₂P₃Ru₂S requires C, 38.65; H, 2.85; N, 10.10; S, 2.10%). IR: 1604vs, 1573s, 1163s, 844 (br), 765vs, 731s, 559vs and 344ms cm⁻¹; Λ_{M} (MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 410 Ω^{-1} cm² mol¹. Complex 9 (Found: C, 42.20; H, 2.70; N, 9.50; S, 2.10. C₅₇H₄₃ClF₁₈N₁₁O₂P₃Ru₂S requires C, 42.30; H, 2.70; N, 9.50; S, 2.00%). IR 1634s, 1569ms, 1149s, 830 (br), 775s, 722ms and 559vs cm⁻¹; $\Lambda_{\rm M}$ (MeCN, 2 × 10⁻⁴ mol dm⁻³, $20 \,^{\circ}\text{C}) = 410 \,\Omega^{-1} \,\mathrm{cm}^2 \,\mathrm{mol}^{-1}$

[(bipy)₂Ru(pzpys)Ru(bipy)₂(NO₂)][PF₆]₃·2H₂O 10. The compound [Ru(bipy)₂Cl₂]·2H₂O (0.520 g, 1 mmol) was refluxed in ethanol-water (2:1, 30 cm³) for 2 h, then [Ru(bipy)₂(pzpys)·(NO₂)][PF₆]₂·H₂O (0.811 g, 1 mmol) was added. The solution was protected from light and stirred for 2 d. The precipitation of a dark red solid and the preparation of the chromatography column were as described for **8**. A first band of 3 was eluted with acetone-toluene (2:1). Elution with acetone gave a purple band which was concentrated and precipitated with diethyl ether. Yield: *ca.* 30% (Found: C, 38.40; H, 2.80; N, 10.80; S, 2.15. C₄₉H₄₃F₁₈N₁₂O₄P₃Ru₂S require C, 38.40; H, 2.85; N, 10.95; S, 2.10%). IR: 1629ms, 1605s, 1569ms, 1343s, 1314s, 1298s, 1275s, 1162s, 836vs, 766s, 732ms and 559s cm⁻¹. Δ_M(MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 400 Ω⁻¹ cm² mol⁻¹.

[(phen)₂Ru(pzpys)Ru(bipy)₂Cl][PF₆]₃·2H₂O 11. This binuclear complex was prepared similarly starting from [Ru(phen)₂-(pzpys)][PF₆]₂ (0.47 g, 0.5 mmol) and [Ru(bipy)₂Cl₂]·2H₂O (0.26 g, 0.5 mmol). Yield *ca.* 25% (Found: C, 40.55; H, 2.80; N, 9.65; S, 2.00. C₅₃H₄₃ClF₁₈N₁₁O₂P₃Ru₂S requires C, 40.55; H, 2.75; N, 9.80; S, 2.05%). IR: 1632s, 1604s, 1574s, 1150s, 833 (br), 767s, 724s, 559vs and 344ms cm⁻¹. Λ_{M} (MeCN, 2 × 10⁻⁴ mol dm⁻³, 20 °C) = 410 Ω⁻¹ cm² mol⁻¹.

Results and Discussion

Synthesis and characterization of pzpys

Pyrazin-2-yl 2-pyridyl sulfide was prepared by reaction of equimolar amounts of 2-sulfanyl pyridine and chloropyrazine in the presence of K_2CO_3 . Distillation of the reaction mixture under reduced pressure readily gave the required compound in high yield. It is a yellow oil stable for a long time and well soluble in the most common solvents. Its structure was determined by a combination of elemental analysis, ¹H and ¹³C NMR spectral data.

The ¹H NMR spectrum of pzpys in (CD₃)₂CO (Fig. 1) shows the presence of two isomers (ratio 20:1). This means that at room temperature the possibility of free rotation around the C-S bonds is excluded. Moreover the results of theoretical calculations^{13,17} for di-2-pyridyl sulfide (dps) as well as experimental data^{9,13} indicate that it adopts three equally populated twisted conformations in solution. Molecular models of dps and pzpys show for both compounds similar steric restrictions. However among the three possible rotational conformers 9,13 only two are formed. Furthermore, studies on dps and diphenyl sulfide derivatives indicate a sulfur p_{π} donation towards aromatic rings bearing electron-withdrawing substituents.18 To explain the presence of only two isomers we suggest for pzpys the conformations A and B (Fig. 1) in which the interaction between a sulfur lone pair and the π electrons of the pyrazine ring prevents rotation of this ring which is almost coplanar with the CSC plane, while the pyridine ring is twisted.

The relative orientations of the pyrazine and pyridine rings with respect to the CSC plane should be N(1) inside, N(1') inside and N(1) inside, N(1') outside in A and B, respectively. The ¹H NMR spectrum of the major isomer shows four sets of resonances in the range δ 8.5–7.25 due to the pyridine ring and three sets in the range δ 8.75–8.45 due to the pyrazine ring. The former pattern is consistent with an almost first-order ABMX system, the latter with an ABX system which is fully resolved by a second-order computer-assisted analysis (Table 1).

Complete analysis of the ¹H NMR spectrum of the minor isomer is not possible because some signals are masked by those of the major isomer. However the ¹H NMR data for the minor isomer are of interest. In fact the H^{3'}, H^{4'} and H^{5'} pyridine protons are shielded (δ 7.48, 7.73 and 7.26, respectively) with respect to the same protons of the major isomer (δ 7.53, 7.78 and 7.30, respectively). Conversely the H³ pyrazine proton (δ 8.76) is deshielded with respect to that of the major isomer (δ 8.69). The molecular model of **B** reveals that a diamagnetic anisotropic interaction should occur because of the short distance between the pyridine proton signals of the minor isomer to higher fields. In contrast a paramagnetic anisotropic interaction should occur between the H³ pyrazine proton and the pyridine ring.

The ¹³C NMR spectrum provides further information. In fact the two isomers show overlapped pyrazine carbon signals and different pyridine signals. Furthermore, the pyrazine carbon signals of both isomers (see Table 2) are similar to those of dps^{9b} [δ 157.80 (C²), 150.94 (C⁶), 138.10 (C^{4'}), 126.57 (C^{3'}), 122.77 (C^{5'})]. These data are consistent with a single fixed position of the pyrazine ring because of the interaction between the π electrons of this ring with a lone pair of the sulfur atom.

Looking at the structure of pzpys it is clear that knowledge of its conformational properties is a potential useful tool for the prediction of the stereochemistry of its co-ordination compounds. Conformation A is suitable to give mononuclear complexes in which the monoco-ordinating (N⁴ pyrazine atom) or chelating binding site (N¹ pyrazine and N pyridine atom) is

Scheme 1 Synthetic pathways for the preparation of the complexes: (*i*) Me_2CO , $AgPF_6$, pzpys (excess); (*ii*) N_3^- , pzpys (excess); (*iii*) HPF_6 ; (*iv*) ethanol-water (2:1), pzpys (excess); (*v*) ethanol-water (2:1), $\frac{1}{2}$ pzpys; (*vi*) ethanol-water (2:1), $[Ru(bipy)_2(pzpys)][PF_6]_2$, $[Ru(bipy)_2(pzpys)][PF_6]_2$

As shown in Scheme 1 the $[Ru(bipy)_2(pzpys)Cl][PF_6]$ 1 and $[Ru(dps)_2(pzpys)Cl][PF_6]$ 2 complexes have been obtained by treating $[Ru(bipy)_2Cl_2]$ or $[Ru(dps)_2Cl_2]$ dissolved in acetone with AgPF₆ (ratio 1:1) in the presence of a large excess of pzpys, while $[Ru(bpy)_2(pzpys)(NO_2)][PF_6]$ 3 and $[Ru(dps)_2(pzpys)(NO_2)][PF_6]$ 4 have been prepared through solvento species generated *in situ* from the nitrosyl derivatives. Compounds 1 and 2 can be prepared in the same way from $[Ru(bipy)_2(NO)Cl][PF_6]_2$ and $[Ru(dps)_2(NO)Cl][PF_6]_2$, respectively. Further reaction of 3 with HPF₆ leads to the

formation of $[Ru(bipy)_2(pzpys)(NO)][PF_6]_3$ 5 whereas the same reaction of 4 gives an unstable product. All the above complexes contain pzpys co-ordinated in a monodentate fashion. The compounds $[Ru(bipy)_2(pzpys)][PF_6]_2$ 6 and [Ru(phen)₂(pzpys)][PF₆]₂ 7 containing pzpys chelated to ruthenium can be obtained by several methods. In fact the reaction of 5 with the azide ion (or 1 with $AgPF_6$) in 1:1 ratio gives 6 (see also the syntheses of 1, 8 and 9 in the Experimental section). However the synthetic pathway (iv) gives 6 and 7 in higher yields. The binuclear complexes [(bipy)2Ru(pzpys)Ru-(bipy)₂Cl][PF₆]₃ 8 and [(phen)₂Ru(pzpys)Ru(phen)₂Cl][P- F_{6} 9 were obtained straightforwardly from $[Ru(bipy)_2Cl_2]$ or [Ru(phen)₂Cl₂] and pzpys. By treating [Ru(bipy)₂Cl₂] with the mononuclear complex 3, containing the monodentate pzpys, the complex [(bipy)₂Ru(pzpys)Ru(bipy)₂(NO₂)][PF₆]₃ was obtained, while from $[Ru(bipy)_2Cl_2]$ and the mononuclear complex 6 or 7 containing chelated pzpys the complexes $[L_2Ru(pzpys)Ru(bipy)_2Cl][PF_6]_3$ (L = bipy or phen) were prepared. In contrast, no tractable products were obtained under comparable conditions from the reactions between $[Ru(bipy)_2Cl_2]$ and $[Ru(dps)_2(pzpys)X][PF_6]$ (X = Cl or NO_2).

All the compounds are soluble in methanol, acetone and acetonitrile. Most are stable for some months in the solid state and for some days in solution; 5 and 9 are much less stable in solution (*ca.* 20 and 60 min, respectively).

NMR spectroscopy

Compounds 1–4, containing monodentate pzpys, consistent with their *cis* configuration, have five inequivalent pyridine rings which give five ABMX systems in the ¹H NMR spectrum and 25 carbon signals in the ¹³C NMR spectrum. Moreover the pyrazine ring produces an ABX system and four carbon signals. Complete assignment of the signals present in the ¹H NMR spectra is mainly based on the analysis of the correlation (COSY) spectra (which clarify the connectivity patterns of the rings) and ring-current effects.¹⁹

We assign the more deshielded $H^{6''}$ protons, observed for compounds 1-4 in the range δ 9.85-9.60, to ring a next to a Cl or

NO₂ group (Fig. 2 and Table 1). Consequences of the ringcurrent effects are: (*i*) a moderate upfield shift of the *o*-protons (range δ 9.07–8.78) assigned to ring b above the pyrazine ring; (*ii*) a higher upfield shift of the *o*-protons lying above the plane of the adjacent bipy rings (H^{6"} of rings c and d, Fig. 2 and Table 1); (*iii*) a downfield shift of the pyridine protons at the 3 position of bipy (rings a–d) of 1 and 3 relative to those of the pyridine ring of dps in 2 and 4. The last shift may be also due to a steric interaction between the H^{3"} protons of the coplanar rings. The assignment of the proton pyrazine signals of pzpys follows from COSY spectra as well as the splitting patterns.²⁰ In fact when pzpys is co-ordinated to the ruthenium centre the H³ and H⁵ protons are not coupled to each other whereas they are coupled with H⁶.

On comparing the ¹H NMR spectra of compounds in which pzpys is monodentate with those of compounds containing chelated pzpys, we observe (Table 1) that the H⁶ pyrazine protons of 1-4 fall in the range δ 8.3-8.5 whereas in 6 and 7 these resonances are shifted to lower frequencies in agreement with the N¹ co-ordination of the pyrazine ring and as a consequence of the diamagnetic anisotropic effect of the adjacent ring of bipy (or phen). A similar effect, when pzpys is chelated, shields the H^{6'} proton of the pyridine ring of pzpys. Conversely the H³ proton resonances, which for the chelated compounds 6 and 7 are observed at high frequencies (δ 9.04 and 9.05, respectively), are shifted to lower frequencies for complexes 1-4. All the above results suggest that in 6 and 7 pzpvs is chelated to the ruthenium centre through the N¹pyrazine and the N-pyridine atoms, while in 1-4 co-ordination occurs via the N⁴ atom of the pyrazine ring. Furthermore, broad signals for the H^3 and H^5 protons in the ¹H NMR spectra of 1 and 3 suggest that a rotation of the pyrazine ring around the Ru-N⁴ bond is operative. Unfortunately this process is not frozen even at low temperature.

In the ¹³C NMR spectra of complexes 1 and 3 the C^{6"}, C^{4"}, C^{5"} and C^{3"} signals of bipy are in the ranges δ 154.5–152.0, 139.0–136.5, 128.0–126.5 and 125.0–123.5, respectively. In the spectrum of the dicationic compound 6 the above carbon atoms are significantly deshielded in accordance with the increasing transfer of electron density from bipy to the metal. Also in the dps derivatives (2–4) the pyridine carbons are deshielded as observed in similar compounds.^{9a}

The ¹³C NMR spectra confirm the co-ordination mode of pzpys in compounds 1-4, 6 and 7. The pyridine and pyrazine carbon signals of pzpys were assigned with the help of C-H correlation experiments (Fig. 3). The N(1) co-ordination of pyrazine and the N co-ordination of pyridine in chelated compounds 6 and 7 deshield the C⁶ pyrazine and C^{6'} pyridine carbons. In particular, the pyrazine C⁶ signals are up to 6 ppm higher than that of free pzpys. Furthermore the C⁶ carbons are deshielded with respect to the C³ and C⁵ pyrazine carbons, whereas in the monodentate compounds the opposite trend occurs (Fig. 3).

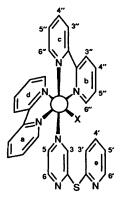

Fig. 2 View of the $[Ru(bipy)_2(pzpys)X]^+$ cation in complexes 1 and 3 with atomic numbering

Electronic spectroscopy

The UV/VIS absorption maxima of the complexes are reported in Table 3. The spectra of all compounds contain intense absorptions in the range 295–220 nm assigned as π - π^* ligand transitions. They also contain lower-energy bands assigned as metal-to-ligand charge-transfer (m.l.c.t.) transitions. For the mononuclear compounds containing monodentate pzpys the absorption spectra are similar to those of the corresponding pyrazine compounds.^{3a,b} In particular the m.l.c.t. bands for [Ru(bipy)₂(pzpys)Cl][PF₆] are observed at 478, 458, 393 and 335 nm and the same number of bands of similar energy are observed for [Ru(bipy)₂(pyz)Cl]- $[PF_6]$ (pyz = pyrazine).^{3a} Moreover the band at 393 nm can be assigned to the $d \rightarrow \pi^*$ (pzpys) transition just as that at 385 nm for the pyrazine derivative is assigned to the d $\longrightarrow \pi^*$ (pyrazine) transition. For the [Ru(dps)₂(pzpys)Cl][PF₆] and [Ru(dps)₂(pzpys)(NO₂)][PF₆] complexes blue shifts of the m.l.c.t. bands (415 and 373 nm, respectively) are observed

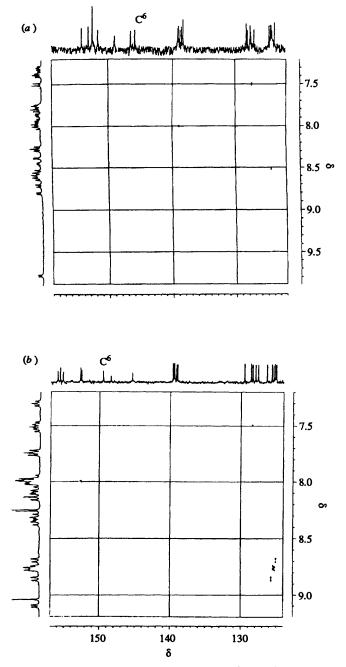

Fig. 3 The C-H correlation NMR spectra of $[Ru(bipy)_2(NO_2)-(pzpys)][PF_6](a)$ and $[Ru(bipy)_2(pzpys)][PF_6]_2(b)$

 Table 3

with respect to those of the bipy derivatives in agreement with the suggestion that the dps ligand 9^a is a weaker π acceptor than bipy. Similar bands assigned as $d_{*}(Ru)$ — → π* (dps) transitions have been previously observed for [Ru- $(dps)_2(pyz)X][PF_6]$ complexes $(X = Cl \text{ or } NO_2).^{9a}$ These spectral similarities indicate that the electronic environment at the ruthenium(II) site is little changed by substitution of pyrazine by the monodentate pzpys ligand. Although the exact position of the d $\longrightarrow \pi^*(pzpys)$ transitions for the complexes $[Ru(bipy)_2(pzpys)][PF_6]_2$ and $[Ru(phen)_2(pzpys)][PF_6]_2$ is masked by intense $d \longrightarrow \pi^*(bipy)$ or $d \longrightarrow \pi^*(phen)$ transitions, the slight blue shifts of the last bands with respect to those of [Ru(bipy)₃][PF₆]₂ and [Ru(phen)₃]- $[PF_6]_2^{8a}$ suggest that chelated pzpys is a comparable π -acceptor ligand to bipy (or phen). The spectra of the binuclear compounds are consistent with this. In particular, in the spectrum of [(bipy)₂Ru(pzpys)Ru(bipy)₂Cl][PF₆]₃ the band observed at 540 nm can be assigned to the d $\longrightarrow \pi^*(pzpys)$ transition. The red shift of this band with respect to those of the mononuclear compounds 1 and 6 is attributed to stabilization of the m.l.c.t. excited state by the positive charge of the remote ion. In addition complex 8 exhibits another m.l.c.t. band at 450 nm $\{452 \text{ nm for } [Ru(bipy)_3] [PF_6]_2\}$ in accord with the suggestion that pzpys and bipy are comparable π -acceptor ligands and evidencing that the d $\longrightarrow \pi^*(bipy)$ transition is not influenced by the remote ion. Similar considerations apply on comparing the bi- and mono-nuclear chelated compounds containing 1,10-phenanthroline. The energy of the m.l.c.t. bands of both the bipy and dps derivatives is dependent on the nature of the ligand cis with respect to pzpys. In fact blue shifts are observed on replacing Cl^- by a stronger π -acceptor ligand such as NO₂ or NO. Also in the spectrum of the binuclear compound [(bipy)₂Ru(pzpys)Ru(bipy)₂(NO₂)][PF₆]₃ the m.l.c.t. bands, assigned as d $\longrightarrow \pi^*$ transitions (pzpys, 536 nm, bipy 438 nm) are blue shifted with respect to those of the corresponding compound containing Cl.

Electrochemistry

A preliminary electrochemical investigation of the redox properties of the present complexes has been performed on the mononuclear derivatives 1-3, 6 and the binuclear species 8.

Fig. 4 shows the cyclic voltammetric anodic profile exhibited by complex 1 in acetonitrile solution. As confirmed by controlled-potential coulometry ($E_w = +1.1$ V), this process involves a chemically reversible one-electron removal, which we confidently assign to the Ru^{II}–Ru^{III} couple. Closely grouped reduction waves typical of processes centred on the π conjugated ligand are present in the cathodic region from -1.3to -2.0 V.²¹

Analysis ²² of the cyclic voltammetric responses corresponding to the anodic process at various scan rates from 0.02 to 2.00 V s⁻¹ shows that the i_{pc}/i_{pa} ratio is constantly equal to 1 : 1, $i_{pa}v^{-\frac{1}{2}}$

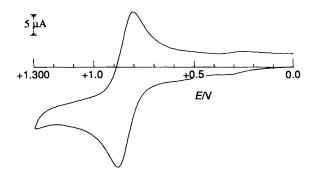

Fig. 4 Cyclic voltammogram recorded at a platinum electrode for a MeCN solution containing complex 1 (1.4×10^{-3} mol dm⁻³) and [NEt₄][ClO₄] (0.1 mol dm⁻³). Scan rate 0.2 V s⁻¹

is substantially constant and the peak-to-peak separation progressively increases from 82 to 216 mV. Taking into account that under the same experimental conditions the electrochemically reversible oxidation of ferrocene ($E^{\circ\prime} = +0.38$ V) exhibits a progressive ΔE_p increase from 67 to 128 mV, these features are diagnostic of an electrochemically quasi-reversible Ru^{II}-Ru^{III} electron transfer. Significant geometrical reorganization probably occurs upon removing one electron from complex 1.²³

Although qualitatively similar behaviour is displayed by complexes 2, 3 and 6 in cyclic voltammetry, there are some significant differences as far as controlled-potential macroelectrolysis experiments are concerned. In the case of complexes 2 and 3 their electrogenerated dications are not completely stable and decompose to oxidizable species with an overall consumption of two electrons per molecule. On the other hand, the oxidized product of 6 apparently undergoes self-reduction, in that the electrolysis current progressively decreases with time, but after one electron per molecule the residual current remains higher than the background current and even after the consumption of three electrons it does not disappear, although cyclic voltammetric tests coupled to direct-current voltammograms at a platinum electrode with periodical renewal of the diffusion layer do not reveal the presence of unknown species.

Table 4 summarizes the formal electrode potentials for $Ru^{II}-Ru^{II}$ oxidation of all the complexes studied. Comparison between 6 and $[Ru(bipy)_3]^{2+}$ indicates that the new ligand pzpys is somewhat more electron withdrawing than is bipy.

Fig. 5 illustrates the anodic profile of the binuclear complex 8. Step-by-step controlled-potential coulometric tests show that each oxidation process involves one eletron per molecule. Both processes are chemically reversible and their redox potentials are included in Table 4. Since these anodic steps are assigned to the sequence Ru^{II}Ru^{II}-Ru^{II}Ru^{III}-Ru^{III}Ru^{III}, which is rather common for polypyridylruthenium complexes,²⁴ a K_{com} of 2×10^9 is computed, which allows the mixed-valence Ru^{II}Ru^{III} complex to be classified as a completely delocalized Robin-Day Class III compound.²⁵

Conclusion

The data reported indicate that pzpys acts as a very interesting bridging ligand which has a conformation (A) favouring onestep or stepwise assembly of RuL₂ and RuL₂X subunits. This is an interesting way to obtain asymmetric binuclear species containing significantly different ruhenium centres. It remains to be established if such differences between the ruthenium polypyridine subunits may play a role in determining selectivity in reactions like the oxidation of polynuclear complexes. Preliminary results show that the complex [(bipy)2Ru- $(pzpys)Ru(bipy)_2Cl][PF_6]_3$ undergoes single-electron oxidation to give a stable mixed-valence compound.
