# Syntheses and structures of novel cyclic and dinuclear organorhodoximes: a homologous series of di- to penta-methylene-bridged complexes $\ddagger$ 

Dirk Steinborn, ${ }^{*} \dagger$ Mario Rausch, Clemens Bruhn, Harry Schmidt and Dieter Ströhl<br>Institut für Anorganische Chemie, Martin-Luther-Universität Halle-Wittenberg, Kurt-Mothes-Strasse 2, D-06120 Halle, Germany

#### Abstract

The compound $\left[\mathrm{Rh}\left(\mathrm{Hdmg}_{2}\left(\mathrm{PPh}_{3}\right)\right]^{-}\left([\mathrm{Rh}]^{-}\right)\right.$, synthesized by reduction of $[\mathrm{Rh}]-\mathrm{Cl}$ with $\mathrm{NaBH}_{4}$ in methanolic KOH , reacted with 1,2 -disubstituted ethanes $\mathrm{XCH}_{2} \mathrm{CH}_{2} \mathrm{X}^{\prime}\left(\mathrm{X} / \mathrm{X}^{\prime}=\mathrm{Cl} / \mathrm{OMe}\right.$ or $\left.\mathrm{Br} / \mathrm{Br}\right)$ forming [ Rh$]-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OMe} 1 \mathrm{a}$ as well as [ Rh$]-\mathrm{Br}$ and ethylene as heterolytic fragmentation products. Heterolytic fragmentation of $\mathbf{1 a}$ enforced by protonation with acids $\left(\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}, \mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}\right)$ generated $\mathrm{MeOH}, \mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}$ and [ Rh$]-\mathrm{O}_{3} \mathrm{SCF}_{3}$ and $[\mathrm{Rh}]-\mathrm{O}_{2} \mathrm{CCD}_{3}$, respectively. Reaction of $[\mathrm{Rh}]^{-}$with $\mathrm{XCH}_{2} \mathrm{CH}_{2} \mathrm{X}^{\prime}\left(\mathrm{X} / \mathrm{X}^{\prime}=\mathrm{Cl} / \mathrm{Cl}, \mathrm{Cl} / \mathrm{Br}\right.$ or $\mathrm{Cl} / \mathrm{OPh})$ afforded the dinuclear complex $[\mathrm{Rh}] \mathrm{CH}_{2} \mathrm{CH}_{2}[\mathrm{Rh}]$ 2a. The anion $[\mathrm{Rh}]^{-}$reacted with $\mathrm{Cl}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{Cl}$ to give [ Rh ] $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Cl} 1 \mathbf{1 b}$, whereas $\mathrm{Br}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{Br}$ was reacted with excess and equimolar amounts of [ Rh ] , yielding $[\mathrm{Rh}] \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}[\mathrm{Rh}] \mathbf{2 b}$ and $\left[\mathrm{Rh}\left\{\left(\mathrm{CH}_{2}\right)_{3} \mathrm{ON}=\mathrm{C}(\mathrm{Me}) \mathrm{C}(\mathrm{Me})=\mathrm{NO}\right\}(\mathrm{Hdmg})\left(\mathrm{PPh}_{3}\right)\right] \mathbf{3 b}$, respectively. Similar reactions carried out with $\mathrm{Br}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{Br}(n=4$ or 5$)$ yielded $[\mathrm{Rh}]-\left(\mathrm{CH}_{2}\right)_{5} \mathrm{Br} \mathbf{1 d}$, $[\mathrm{Rh}]\left(\mathrm{CH}_{2}\right)_{n}[\mathrm{Rh}](n=4 \mathbf{2 c}$ or 5 2d) and $\left[\mathrm{Rh}\left\{\left(\mathrm{CH}_{2}\right)_{n} \mathrm{ON}=\mathrm{C}(\mathrm{Me}) \mathrm{C}(\mathrm{Me})=\mathrm{NO}\right\}(\mathrm{Hdmg})\left(\mathrm{PPh}_{3}\right)\right](n=43 \mathrm{c}$ or 53 d$)$, respectively. All complexes were fully characterized by NMR spectroscopy ( ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}$ ). The ${ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of dinuclear complexes $\mathbf{2 a}$ and $\mathbf{2 b}$ exhibit typical AA' patterns of $\mathrm{AA}^{\prime} \mathrm{XX}^{\prime}$ systems ( $\mathrm{A}={ }^{31} \mathrm{P}, \mathrm{X}={ }^{103} \mathrm{Rh}$ ) due to considerable ${ }^{5} J\left({ }^{31} \mathrm{P}^{-31} \mathrm{P}\right)$ and ${ }^{6} J\left({ }^{31} \mathrm{P}-{ }^{31} \mathrm{P}\right)$ couplings ( $36.7,11.2 \mathrm{~Hz}$ ), respectively. The crystal structures of the dinuclear rhodoximes $\mathbf{2 a}-\mathbf{2 c}$ and of the cyclic organorhodoxime $\mathbf{3 b}$ have been determined. The two $(\mathrm{Hdmg})_{2}$ planes in the di- and tetra-methylenebridged complexes 2a and 2c are parallel with distances of 4.5 (2a) and $7.1 \AA$ (2c), respectively, and exhibit an ecliptic conformation. In the trimethylene-bridged complex $\mathbf{2 b}$, the two $(\mathrm{Hdmg})_{2}$ planes include an angle of $45.0(1)^{\circ}$ and exhibit a staggered conformation, which minimizes electrostatic repulsion between the $\mathrm{O}-\mathrm{H}-\mathrm{O}$ moieties and the steric interference between two methyl groups. In all three complexes the oligo-methylene bridges are fully staggered. In $\mathbf{3} \mathbf{b}$ the six-membered ring (1-oxa-2-aza-3-rhodacyclohexane) exhibits a distorted chair conformation. The distance between the two O atoms in the $\mathrm{O}-\mathrm{H}-\mathrm{O}$ bridge $[\mathrm{O}(2) \cdots \mathrm{O}(3) 2.58(1) \AA]$ is distinctly shorter than those that are not connected via a hydrogen bridge $[\mathrm{O}(1) \cdots \mathrm{O}(4) 3.30(1) \AA$ Å.

Hydrocarbon-bridged dinuclear complexes of transition metals can be considered as connections between mononuclear organometallic compounds and organometallic clusters and might be intermediates or model compounds in catalytic processes. Therefore, they have been the subject of intensive studies in the last years and reviews of salient aspects of these complexes have appeared. ${ }^{1}$ In 1963 King $^{2}$ reported the first simple saturated hydrocarbon-bridged complexes of the type $\mathrm{M}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{M}^{\prime}$ without metal-metal bonds or additional bridging ligands. Since then some complexes have been prepared with oligomethylene chains linking two $\mathrm{L}_{x} \mathrm{M}$ centers using monodentate (like $\mathrm{C}_{5} \mathrm{H}_{5}, \mathrm{CO}, \mathrm{PR}_{3}$ ) or macrocyclic [like porphyrins, $(\mathrm{Hdmg})_{2}\left(\mathrm{H}_{2} \mathrm{dmg}=\right.$ dimethylglyoxime $)$ ] ligands L. Only a few, having monodentate auxiliary ligands, have been structurally characterized. ${ }^{3}$ The only example in the Cambridge Structural Database ${ }^{4}$ where the metals have macrocyclic ligands is the tetramethylene-bridged vitamin $\mathrm{B}_{12}$ dimer. ${ }^{5}$ Here we report the synthesis, reactivity, characterization and structures of organorhodoximes of the type $[\mathrm{Rh}]\left(\mathrm{CH}_{2}\right)_{n}[\mathrm{Rh}]$ with $n=2-5$, a homologous series of di- to penta-methylene-bridged complexes.

Organorhodoximes $\left[\mathrm{Rh}(\mathrm{Hdmg})_{2}(\mathrm{~L}) \mathrm{R}\right](\mathrm{L}=$ axial base $)$, first prepared by Weber and Schrauzer, ${ }^{6}$ have been extensively investigated. None but the triphenylphosphine derivatives $\left(\mathrm{L}=\mathrm{PPh}_{3}\right)$ was synthesized with all basic types of hydrocarbyl ligands R (sp ${ }^{3}$ : alkyl; sp²: vinyl, aryl, allenyl; sp: alkynyl) and

[^0]with functionalized organo ligands such as $\left(\mathrm{CH}_{2}\right)_{n} \mathrm{YR}_{x}$ and $\mathrm{CH}=\mathrm{CHYR}_{x}\left(\mathrm{Y}=\right.$ element of Groups 15-17). ${ }^{7}$ The electronic structure in the linear complex fragment $\mathrm{P}-\mathrm{Rh}-\mathrm{C}$ can be studied by NMR spectroscopy $\left(I=\frac{1}{2}:{ }^{103} \mathrm{Rh},{ }^{31} \mathrm{P},{ }^{13} \mathrm{C}\right) .{ }^{8.9}$ The coupling constants ${ }^{1} J\left({ }^{103} \mathrm{Rh}-{ }^{31} \mathrm{P}\right)$ and bond lengths $d(\mathrm{Rh}-\mathrm{P})$ were used to study the NMR and structural trans influence of R. ${ }^{9,10}$

To date, many mononuclear organorhodoximes have been described, ${ }^{7,11}$ but there is only one report of a dinuclear hydrocarbon-bridged rhodoxime, namely $\left[\left\{\mathrm{K}(\mathrm{MeOH})_{2}\right\}_{2}-\right.$ $\left.\left\{\left(\mathrm{Ph}_{3} \mathrm{P}\right)(\mathrm{dmg})(\mathrm{Hdmg}) \mathrm{Rh}-\mathrm{CH}=\mathrm{CH}-\mathrm{Rh}(\mathrm{dmg})(\mathrm{Hdmg})\left(\mathrm{PPh}_{3}\right)\right\}\right]$, which was also structurally characterized. ${ }^{12}$

Furthermore, in organorhodoximes the pseudo-macrocyclic equatorial ligand, $(\mathrm{Hdmg})_{2}$, usually does not undergo reactions except for protonation/deprotonation or functionalization of the $\mathrm{O}-\mathrm{H}-\mathrm{O}$ groups. ${ }^{13}$ Recently, reduction of an oxime to an imine group was observed upon reaction of $\left[\mathrm{Rh}(\mathrm{Hdmg})_{2}\right]^{-}$with phosphines. ${ }^{14}$ Here, we also report unprecedented substitution reactions to give rhodacycles via $\omega$-halogenoalkylrhodoximes as intermediates.

## Experimental

All reactions with $R h^{1}$ were carried out under argon using Schlenk techniques. Solvents were dried and distilled under argon according to standard methods. The compound [Rh$\left.(\mathrm{Hdmg})_{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}\right]([\mathrm{Rh}]-\mathrm{Cl})$ was prepared by a published method. ${ }^{15}$ The other chemicals were commercial materials used without further purification.

Microanalyses ( $\mathrm{C}, \mathrm{H}, \mathrm{N}, \mathrm{Cl}, \mathrm{Br}$ ) were performed by the

Table 1 Synthesis of organorhodoximes 1-3

University of Halle microanalytical laboratory using a CHNS932 (LECO) and vario EL (elementar Analysensysteme) elemental analyser, respectively. The ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR spectra were obtained with Varian Unity 500 and Gemini 200 spectrometers ( ${ }^{1} \mathrm{H}$ at $499.88 / 199.97 \mathrm{MHz},{ }^{13} \mathrm{C}$ at $125.71 / 50.289 \mathrm{MHz}$, ${ }^{31} \mathrm{P}$ at 80.95 MHz$)$. Solvent signals ( ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ ) were used as internal standards, $\delta\left({ }^{31} \mathrm{P}\right)$ relative to external $\mathrm{H}_{3} \mathrm{PO}_{4}(85 \%)$. Heteronuclear multiple quantum correlation (HMQC) spectra were recorded on Varian Unity 500 spectrometer operating at 125.71 MHz for ${ }^{13} \mathrm{C}$ by ${ }^{1} \mathrm{H}$ observation. Thermoanalytic investigations were performed on a STA 409C (Netzsch) instrument in a helium atmosphere. A CP9000 (Chrompack) chromatograph was used for gas chromatographic analyses.

## Preparations

[Rh]- $\left(\mathrm{CH}_{2}\right)_{2} \mathrm{OMe} 1 \mathrm{a},[\mathrm{Rh}]-\left(\mathrm{CH}_{2}\right)_{3} \mathrm{Cl} 1 \mathrm{lb}$ and $[\mathrm{Rh}]-\left(\mathrm{CH}_{2}\right)_{5} \mathrm{Br}$ 1d. To a solution of $[\mathrm{Rh}]-\mathrm{Cl}(957 \mathrm{mg}, 1.52 \mathrm{mmol})$ in methanolic $\mathrm{KOH}\left(75 \mathrm{~cm}^{3}, 0.15 \mathrm{~m}\right)$ was added dropwise a solution of $\mathrm{NaBH}_{4}$ ( $76 \mathrm{mg}, 2.00 \mathrm{mmol}$ ) in methanolic $\mathrm{KOH}\left(25 \mathrm{~cm}^{3}, 0.15 \mathrm{~m}\right.$ ) and stirred for 2 h at $20^{\circ} \mathrm{C}$ to give a deep violet solution of $[\mathrm{Rh}]^{-}$. To this a solution of $\mathrm{Cl}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{OMe}, \mathrm{Cl}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{Cl}$ or $\mathrm{Br}\left(\mathrm{CH}_{2}\right)_{5} \mathrm{Br}(n$ mmol , see Table 1) in methanol ( $20 \mathrm{~cm}^{3}$ ) was added within $t_{\mathrm{add}}$ (see Table 1). After the mixture had turned yellow ( $t_{\text {react }}$, Table 1) stirring was continued for 30 min and water $\left(100 \mathrm{~cm}^{3}\right)$ was added. In the case of compounds $\mathbf{1 a}$ and $\mathbf{1 b}$ the reaction mixture was neutralized ( $\mathrm{pH} 7-8$ ) with solid $\mathrm{CO}_{2}$. After 12-24 h the yellow precipitate was filtered off, washed with diethyl ether ( $\mathbf{1} \mathbf{a}$, 1d) or ethanol (1b) and recrystallized.

Compound 1a: m.p. $183-188^{\circ} \mathrm{C}$ (decomp.) (Found: C, 53.4; $\mathrm{H}, 5.5 ; \mathrm{N}, 8.3 . \mathrm{C}_{29} \mathrm{H}_{36} \mathrm{~N}_{4} \mathrm{O}_{5} \mathrm{PRh}$ requires $\mathrm{C}, 53.2 ; \mathrm{H}, 5.5 ; \mathrm{N}$, $8.5 \%) ; \delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 1.24\left(2 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 1.80[12 \mathrm{H}$, d, $\left.{ }^{5} J(\mathrm{PH}) 2.15 \mathrm{~Hz}, 4 \mathrm{CH}_{3}\right], 3.12\left(2 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}\right), 3.12(3 \mathrm{H}, \mathrm{s}$, $\mathrm{OCH}_{3}$ ) and $7.3\left(15 \mathrm{H}, \mathrm{m}, 3 \mathrm{C}_{6} \mathrm{H}_{5}\right)$. Compound 1b: m.p. 160 $165^{\circ} \mathrm{C}$ (decomp.) (Found: C, 51.6; H, 5.2; Cl, 5.2; N, 8.0. $\mathrm{C}_{29} \mathrm{H}_{35} \mathrm{ClN}_{4} \mathrm{O}_{4} \mathrm{PRh}$ requires C, 49.2; $\mathrm{H}, 5.0 ; \mathrm{Cl}, 5.0 ; \mathrm{N}, 7.9 \%$ ); $\delta_{\mathrm{H}}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 1.10\left(2 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 1.39(2 \mathrm{H}, \mathrm{m}$, $\left.\beta-\mathrm{CH}_{2}\right), 1.83\left[12 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 2.15,4 \mathrm{CH}_{3}\right], 3.25\left[2 \mathrm{H}, \mathrm{t},{ }^{3} J(\mathrm{HH})\right.$ $7.23 \mathrm{~Hz}, \gamma-\mathrm{CH}_{2}$ ] and $7.3\left(15 \mathrm{H}, \mathrm{m}, 3 \mathrm{C}_{6} \mathrm{H}_{5}\right)$. Compound $\mathbf{1 d}$ : m.p. $145-147^{\circ} \mathrm{C}$ (decomp.) (Found: C, 49.0; H, 5.4; Br, 11.3; N, 7.2. $\mathrm{C}_{31} \mathrm{H}_{39} \mathrm{BrN}_{4} \mathrm{O}_{4} \mathrm{PRh}$ requires $\mathrm{C}, 49.9 ; \mathrm{H}, 5.3 ; \mathrm{Br}, 10.7 ; \mathrm{N}, 7.5 \%$ ); $\delta_{\mathrm{H}}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 0.99\left(2 \mathrm{H}, \mathrm{m}, \gamma-\mathrm{CH}_{2}\right), 1.18(4 \mathrm{H}, \mathrm{m}$, $\left.\alpha-, \beta-\mathrm{CH}_{2}\right), 1.69\left[2 \mathrm{H}\right.$, qnt, $\left.{ }^{3} J(\mathrm{HH}) 7.30, \delta-\mathrm{CH}_{2}\right], 1.81[12 \mathrm{H}, \mathrm{d}$, $\left.{ }^{5} J(\mathrm{PH}) 1.95,4 \mathrm{CH}_{3}\right], 3.25\left[2 \mathrm{H}, \mathrm{t},{ }^{3} J(\mathrm{HH}) 7.03 \mathrm{~Hz}, \varepsilon-\mathrm{CH}_{2}\right]$ and $7.3\left(15 \mathrm{H}, \mathrm{m}, 3 \mathrm{C}_{6} \mathrm{H}_{5}\right)$.
$[\mathrm{Rh}]\left(\mathrm{CH}_{2}\right)_{n}[\mathrm{Rh}] \mathbf{2 a - 2 d}$ and $\left[\mathbf{R h}\left\{\left(\mathrm{CH}_{2}\right)_{n} \mathrm{ON}=\mathbf{C}(\mathrm{Me}) \mathrm{C}(\mathrm{Me})=\mathrm{N}-\right.\right.$ $\left.\mathbf{O \}}(\mathbf{H d m g})\left(\mathbf{P P h}_{3}\right)\right] \mathbf{3 b - 3 d}$. To a stirred solution of $[\mathrm{Rh}]^{-}(1.52$ mmol ) in methanolic $\mathrm{KOH}\left(100 \mathrm{~cm}^{3}, 0.15 \mathrm{~m}\right)$, prepared as described above, was added within $t_{\text {add }}$ (see Table 1) a solution of $\mathrm{X}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{X}\left(n \mathrm{mmol}\right.$, see Table 1) in methanol $\left(20 \mathrm{~cm}^{3}\right)$. After the mixture had turned yellow ( $t_{\text {react }}$, Table 1), stirring was continued for 30 to 60 min and water $\left(100 \mathrm{~cm}^{3}\right)$ was added.

After 12-24 h the precipitate was filtered off. In the case of compound 2a, without adding water, the precipitate was washed with acetone $\left(2 \times 10 \mathrm{~cm}^{3}\right)$ and dried in vacuo; for $\mathbf{2 b}-2 d$, the yellow precipitate was thoroughly washed with acetone (2b) or diethyl ether ( $\mathbf{2 c}, \mathbf{2 d}$ ) and recrystallized. In the case of $\mathbf{3 b}$, after addition of water, the reaction mixture was neutralized with solid $\mathrm{CO}_{2}(\mathrm{pH} 7-8)$. The precipitate was filtered off, washed with diethyl ether $\left(2 \times 5 \mathrm{~cm}^{3}\right)$ and recrystallized. For 3 c and 3d, the precipitate was extracted three times with $10 \mathrm{~cm}^{3}$ acetone (3c) or ether (3d). The extract was dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and concentrated. The orange precipitate was recrystallized (3c) and dissolved in acetone and reprecipitated with ether (three times) (3d).
Compound 2a: $T_{\text {dec }} 215-220^{\circ} \mathrm{C}$ (Found: C, 52.9; H, 5.1; N, 9.0. $\mathrm{C}_{54} \mathrm{H}_{62} \mathrm{~N}_{8} \mathrm{O}_{8} \mathrm{P}_{2} \mathrm{Rh}_{2}$ requires $\mathrm{C}, 53.2 ; \mathrm{H}, 5.1 ; \mathrm{N}, 9.2 \%$ ); $\delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}-\mathrm{MeOH} 15: 1\right) 1.11\left(4 \mathrm{H}, \mathrm{m}, 2 \alpha-\mathrm{CH}_{2}\right)$, $1.69\left[24 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 1.71 \mathrm{~Hz}, 8 \mathrm{CH}_{3}\right]$ and $7.2(30 \mathrm{H}, \mathrm{m}, 6$ $\mathrm{C}_{6} \mathrm{H}_{5}$ ). Compound 2b: $T_{\text {dec }} 180-190^{\circ} \mathrm{C}$ (Found: C, 53.3; H, 5.6; N, 9.2. $\mathrm{C}_{55} \mathrm{H}_{64} \mathrm{~N}_{8} \mathrm{O}_{8} \mathrm{P}_{2} \mathrm{Rh}_{2}$ requires C, 53.6; H, 5.2; N , $9.1 \%) ; \delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 0.58\left(2 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}\right), 0.95$ ( 4 $\left.\mathrm{H}, \mathrm{m}, 2 \alpha-\mathrm{CH}_{2}\right), 1.80\left[24 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 1.96 \mathrm{~Hz}, 8 \mathrm{CH}_{3}\right]$ and $7.2\left(30 \mathrm{H}, \mathrm{m}, 6 \mathrm{C}_{6} \mathrm{H}_{5}\right)$. Compound 2c: $T_{\text {dec }} 240-245^{\circ} \mathrm{C}$ (Found: C, 52.6; H, 5.2; N, 8.6. $\mathrm{C}_{56} \mathrm{H}_{66} \mathrm{~N}_{8} \mathrm{O}_{8} \mathrm{P}_{2} \mathrm{Rh}_{2}$ requires C, $53.9 ; \mathrm{H}, 5.3 ; \mathrm{N}, 9.0 \%) ; \delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 0.71(4 \mathrm{H}, \mathrm{m}, 2$ $\left.\beta-\mathrm{CH}_{2}\right), 1.07\left(4 \mathrm{H}, \mathrm{m}, 2 \alpha-\mathrm{CH}_{2}\right), 1.76\left[24 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 2,15\right.$ $\mathrm{Hz}, 8 \mathrm{CH}_{3}$ ] and $7.2\left(30 \mathrm{H}, \mathrm{m}, 6 \mathrm{C}_{6} \mathrm{H}_{5}\right)$. Compound 2d: $T_{\text {dec }}$ 205-210 ${ }^{\circ} \mathrm{C}$ (Found: C, 52.9; H, 5.7; N, 8.3. $\mathrm{C}_{57} \mathrm{H}_{68} \mathrm{~N}_{8} \mathrm{O}_{8} \mathrm{P}_{2} \mathrm{Rh}_{2}$ requires C, $54.3 ; \mathrm{H}, 5.4 ; \mathrm{N}, 8.9 \%) ; \delta_{\mathrm{H}}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 0.77$ $\left(4 \mathrm{H}, \mathrm{m}, 2 \beta-\mathrm{CH}_{2}\right), 0.90\left(2 \mathrm{H}, \mathrm{m}, \gamma-\mathrm{CH}_{2}\right), 1.09(4 \mathrm{H}, \mathrm{m}, 2$ $\left.\alpha-\mathrm{CH}_{2}\right), 1.81\left[24 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 1.55 \mathrm{~Hz}, 8 \mathrm{CH}_{3}\right]$ and $7.3(30 \mathrm{H}, \mathrm{m}$, $6 \mathrm{C}_{6} \mathrm{H}_{5}$ ).

Compound 3b: m.p. $170-172{ }^{\circ} \mathrm{C}$ (decomp.) (Found: C, 52.6; $\mathrm{H}, 5.3 ; \mathrm{N}, 9.0 . \mathrm{C}_{29} \mathrm{H}_{34} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{PRh}$ requires C, 54.7 ; $\mathrm{H}, 5.4 ; \mathrm{N}$, $8.8 \%$ ); $\delta_{\mathrm{H}}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 1.25 / 1.49\left(2 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 1.25 /$ $2.18\left(2 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}\right), 3.82 / 5.08\left(2 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2}\right), 1.49(3 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{CH}_{3}\right), 1.63\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right), 1.79\left[3 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 2.35, \mathrm{CH}_{3}\right], 2.07[3$ $\mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 2.78 \mathrm{~Hz}, \mathrm{CH}_{3}$ ] and $7.3\left(15 \mathrm{H}, \mathrm{m}, 3 \mathrm{C}_{6} \mathrm{H}_{5}\right)$. Compound 3c: m.p. $194-196^{\circ} \mathrm{C}$ (decomp.) (Found: C, 55.0 ; H, 5.5 ; N , 8.4. $\mathrm{C}_{30} \mathrm{H}_{36} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{PRh}$ requires C, 55.4; H, 5.6; N, 8.6\%); $\delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 1.22 / 1.51 / 1.83 / 2.13\left(6 \mathrm{H}, 4 \mathrm{~m}, 3 \mathrm{CH}_{2}\right)$, $1.51\left[3 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 1.18, \mathrm{CH}_{3}\right], 1.65\left[3 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 1.60, \mathrm{CH}_{3}\right]$, $1.79\left[3 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 2.34, \mathrm{CH}_{3}\right], 2.00\left[3 \mathrm{H}, \mathrm{d},{ }^{5} J(\mathrm{PH}) 2.58 \mathrm{~Hz}\right.$, $\left.\mathrm{CH}_{3}\right], 4.15 / 6.45\left(2 \mathrm{H}, 2 \mathrm{~m}, \mathrm{OCH}_{2}\right)$ and $7.3\left(15 \mathrm{H}, \mathrm{m}, 3 \mathrm{C}_{6} \mathrm{H}_{5}\right)$. Compound 3d: $T_{\text {dec }} 215-220^{\circ} \mathrm{C}$; $\delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 0.8-2.3$ $\left(20 \mathrm{H}, 4 \mathrm{CH}_{2}\right.$ and $\left.4 \mathrm{CH}_{3}\right), 3.90 / 5.40\left(2 \mathrm{H}, 2 \mathrm{~m}, \mathrm{OCH}_{2}\right)$ and 7.4 $\left(15 \mathrm{H}, \mathrm{m}, 3 \mathrm{C}_{6} \mathrm{H}_{5}\right)$.

## Reactions of [Rh]- $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OMe} 1 \mathrm{a}$ with $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ and $\mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}$

To a solution of compound $\mathbf{1 a}(100 \mathrm{mg}, 0,15 \mathrm{mmol})$ in $\mathrm{CDCl}_{3}$ ( $0.7 \mathrm{~cm}^{3}$ ) the appropriate amount of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ and $\mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}$, respectively, was added with a microsyringe. The reactions were

Scheme 1
monitored by NMR $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right)$ spectroscopy. Additionally, ethylene was identified by gas chromatography.

## Thermolysis of $[\mathbf{R h}]\left(\mathrm{CH}_{2}\right)_{n}[\mathbf{R h}]$ 2a-2d

In a sealed tube compound $2(30-50 \mathrm{mg})$ was heated (ca. 4 K $\mathrm{min}^{-1}$ ) to $250^{\circ} \mathrm{C}$. After 20 min the gaseous products were analysed by gas chromatography.

## Crystallography

Suitable single crystals of compounds 2b, 2c and 3a were obtained by recrystallization from the solvent given in Table 1; those of $\mathbf{2 a}$ were grown directly in the reaction mixture. Compound 2 c was mounted in a glass capillary together with mother-liquor. The X-ray measurements were performed on a STOE-Stadi4 four-circle diffractometer (2a) and on a STOE IPDS image-plate system ( $\mathbf{2 b}, \mathbf{2 c}, \mathbf{3 b}$ ), respectively. For 2a the absorption correction was based on several $\psi$ scans ( $T_{\text {min }}, T_{\text {max }}$ $0.83,1.00)$. For all measurements on the image-plate system the reciprocal space was scanned with 133 frames for each of which the crystal was oscillated $1.5^{\circ}$ around the $\varphi$ axis; an absorption correction was carried out numerically.

Crystal data collection and processing parameters are listed in Table 2. The data were corrected for Lorentz-polarization and absorption; equivalent reflections were merged. The structures were solved with direct methods (SHELXS $86{ }^{16}$ ) and subsequent Fourier-difference syntheses revealed the positions of all non-hydrogen atoms which were refined with anisotropic displacement parameters by full-matrix least-squares routines against $F^{2}$ (SHELXL $93{ }^{17}$ ). Hydrogen atoms were placed in calculated positions and refined isotropically with fixed displacement parameters (riding model). The $\mathrm{C}_{2}$ bridge in $\mathbf{2 a}$ is disordered due to a location of atom $\mathrm{C}(27)$ in two positions with the same probability depicted with A and B. Residual electron densities in $\mathbf{2 c}$ are considered to belong to a further solvate molecule which did not refine well and was hence omitted in the refinement.

## Results and Discussion

## Syntheses

$\left(\mathbf{C H}_{2}\right)_{2}$ building block. Bis(dimethylglyoximato)(triphenylphosphine)rhodate( I , , Rh$]^{-}$, was prepared by reduction of [ Rh ]- Cl with $\mathrm{NaBH}_{4}$ in methanolic $\mathrm{KOH} .^{18}$ It reacts with 1,2disubstituted ethanes $\mathrm{XCH}_{2} \mathrm{CH}_{2} \mathrm{X}^{\prime}\left(\mathrm{X}=\mathrm{Cl}\right.$ or $\mathrm{Br} ; \mathrm{X}^{\prime}=\mathrm{Cl}, \mathrm{Br}$, OPh or OMe ) according to Scheme 1. In all cases the first step seems to be a nucleophilic substitution reaction, which can be considered as an oxidative-addition, to give 2 -functionalized ethyl complexes $\mathbf{1}$ as intermediates. With $\mathrm{X}^{\prime}=\mathrm{Cl}$ or OPh a sub-
sequent nucleophilic substitution reaction (oxidative addition) affords the dinuclear ethanediyl complex 2a, see Scheme 1(a). With $\mathrm{X}^{\prime}=\mathrm{Br}$ the intermediate 1 undergoes a heterolytic fragmentation reaction providing $[\mathrm{Rh}]-\mathrm{Br}$ and ethylene [Scheme 1(b)].
The reaction of $[\mathrm{Rh}]^{-}$with $\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{OMe}$ yields [ Rh$]-\mathrm{CH}_{2}-$ $\mathrm{CH}_{2} \mathrm{OMe} 1 \mathrm{a}$ as the main product. Complex 1a is completely stable at room temperature, but with protonation it decomposes to give methanol and ethylene as a result of a heterolytic fragmentation, $c f$. Scheme 2. With $\mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}$ the reaction requires several days ( $\mathbf{1}: \mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}=1: 3$, $t_{2}$ ca. $7 \mathrm{~d} ; \mathbf{1 a}: \mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}=$ $1: 8, t_{\frac{1}{2}} c a .2 \mathrm{~d}$ ). Under the same conditions the ethyl complex [ Rh$]-\mathrm{CH}_{2} \mathrm{CH}_{3}$ is completely stable and shows no $\mathrm{Rh}-\mathrm{C}$ bondsplitting reaction. The strong acid $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ reacts with $\mathbf{1 a}(\mathbf{1 a}:$ $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}=1: 1.5$ ) at room temperature (r.t.) within a few minutes to give ethylene, methanol and $[\mathrm{Rh}]-\mathrm{O}_{3} \mathrm{SCF}_{3}$ as heterolytic fragmentation products.

Scheme $2 \mathrm{HA}=\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ or $\mathrm{CD}_{3} \mathrm{CO}_{2} \mathrm{D}$
Obviously, the reactivity of complexes $[\mathrm{Rh}]-\left(\mathrm{CH}_{2}\right)_{2} \mathrm{X}^{\prime}$ strongly depends upon the nature of substituent $\mathrm{X}^{\prime}$ : good nucleofugal leaving groups ( $\mathrm{Br}^{-}, \mathrm{MeOH}$ ) induce heterolytic fragmentation and poor ones $\left(\mathrm{MeO}^{-}\right)$lead to stable 2functionalized ethyl complexes. An intermediate nucleophilicity of $\mathrm{X}^{\prime}\left(\mathrm{Cl}^{-}, \mathrm{PhO}^{-}\right)$favours a nucleophilic substitution (oxidativeaddition) reaction.
$\left(\mathbf{C H}_{2}\right)_{3}$ building block. 1,3-Dichloropropane undergoes an oxidative-addition reaction with $[\mathrm{Rh}]^{-}$to give the 3 -chloropropylrhodoxime 1b, as the main product ( $58 \%$ yield), see Scheme 1. The analogous reaction with 1,3 -dibromopropane in a molar ratio $c_{\mathrm{Rh}}: c_{\mathrm{Br}(\mathrm{CH})_{3} \mathrm{Br}}=2: 1$ affords the dinuclear propanediyl-bridged complex $\mathbf{2 b}$ ( $51 \%$ yield) and in a molar ratio $c_{\mathrm{Rh}}: c_{\mathrm{Br}\left(\mathrm{CH}_{2}\right) 3 \mathrm{Br}}=1: 1$ the cyclic organorhodoxime $\mathbf{3 b}$ ( $43 \%$ yield). It can be assumed that the 3-bromopropyl complex $\mathbf{1}\left(\mathrm{X}^{\prime}=\mathrm{Br}, n=3\right)$ is an intermediate in these two reactions, see Scheme 1. Considering the greater stability of $\mathrm{C}-\mathrm{Cl}$ bonds compared with $\mathrm{C}-\mathrm{Br}$ bonds, it becomes clear that the 3-chloropropylrhodoxime 1a is stable under ambient reaction conditions. However, the corresponding bromo derivative undergoes a subsequent reaction, either an intramolecular substitution of $\mathrm{Br}^{-}$by the deprotonated dimethylglyoximate ligand to give $\mathbf{3 b}$ or an intermolecular nucleophilic substitution with $[\mathrm{Rh}]^{-}$to give the dinuclear complex $\mathbf{2 b}$.
$\left(\mathbf{C H}_{2}\right)_{n}(\boldsymbol{n}=\mathbf{4}$ or $\mathbf{5})$ building block. As with 1,3-dibromopropane, $\operatorname{Br}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{Br}(n=4$ or 5$)$ reacts with an excess of $[\mathrm{Rh}]^{-}$

* Details in common: Mo-K $\alpha$ radiation $\left(\lambda_{\mathrm{o}}=0.71073 \AA\right), \quad R 1=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right|, \quad w R 2=\left[\Sigma w\left(F_{\mathrm{o}}{ }^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2} / \Sigma w\left(F_{\mathrm{o}}{ }^{2}\right)^{2}\right]^{\frac{1}{2}}, \quad S=\left[\Sigma w\left(F_{\mathrm{o}}{ }^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2} /\right.$ ( $\left.\left.N_{\text {obs }}-N_{\text {param }}\right)\right]^{\frac{1}{2}}$ (based on all data).
$\left(c_{\mathrm{Rh}}: c_{\mathrm{Br}\left(\mathrm{CH}_{2}\right) \mathrm{Br}}=2: 1\right)$ to give the dinuclear butanediyl- and pentanediyl-bridged complexes $[\mathrm{Rh}]\left(\mathrm{CH}_{2}\right)_{n}[\mathrm{Rh}] 2 \mathrm{c}$ and 2d, respectively. The reactions of equimolar amounts yield the rhodacyclic complexes 3c and 3d. The 5-bromopentyl intermediate 1d could be isolated in a good yield ( $40 \%$ ) by fast mixing of $[\mathrm{Rh}]^{-}$with a large excess of 1,5 -dibromopentane $\left(c_{\mathrm{Rh}}: c_{\mathrm{Br}\left(\mathrm{CH}_{2}\right) \mathrm{Br}}=1: 2.6\right)$.

## Properties and stability of complexes

In all the reactions mixtures of complexes are formed as was confirmed by NMR spectroscopy. The dinuclear complexes $\mathbf{2 b}$ $\mathbf{2 d}$ and the cyclic organorhodoximes $\mathbf{3 b} \mathbf{- 3 d}$ especially are products of parallel reactions. Which of them is formed as main product is dependent mainly on the molar ratio $c_{\mathrm{Rh}}: c_{\mathrm{X}\left(\mathrm{CH}_{2}\right) \mathrm{X}}$ used and on the type of halide substituent X. By fractional crystallization of the raw products all complexes are affordable as pure substances except $\mathbf{3 d}$. Owing to its good solubility and the very low yield ( $5 \%$ ), 3d contains about $15 \%$ each of the bromopentyl complex 1d and the dinuclear complex 2d.

All complexes are stable in air and form yellow (1a, 1b, 1d, $\mathbf{2 a}-\mathbf{2 d}, \mathbf{3 b}$ ) and orange ( $\mathbf{3 c}, \mathbf{3 d}$ ) crystals, respectively. The tetramethylene-bridged complex 2c crystallizes as a solvate $\left(\mathbf{2 c} \cdot 6 \mathrm{CHCl}_{3}\right)$ that rapidly loses chloroform in air. The identities of all complexes were confirmed by microanalysis and NMR spectroscopy as well as by crystal structure determinations for $2 \mathrm{a}-2 \mathrm{c}$ and $\mathbf{3 b}$.

All complexes are thermally relatively stable. The dinuclear complexes 2a-2d decompose between 180 and $245^{\circ} \mathrm{C}$ without melting. Thus, the ethanediyl-bridged complex 2a is stable in the solid state at $90^{\circ} \mathrm{C}$ for at least 20 min . In $\mathrm{CDCl}_{3}: \mathrm{MeOH}$ (15:1) at $50^{\circ} \mathrm{C}$ a decomposition takes place to give ethylene and [ Rh$]-\mathrm{Cl}$ within 1 h . The dimeric rhodium(II) complex [Rh]-[Rh] might be an intermediate that reacts rapidly with chloroform to give $[\mathrm{Rh}]-\mathrm{Cl}$ as was shown in a separate experiment. Similarly, an equilibrium was found between $\mathrm{LRh}-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{RhL}\left[\mathrm{L}=\mathrm{N}_{4}\right.$ equatorial ligands like porphyrinate and 1,2 -bis(pyridine-2-
carboxamido)benzene derivatives] and LRh-RhL and ethylene. ${ }^{19}$
Thermolysis of the ethanediyl complex 2 a yields nearly exclusively ethylene and only small amounts of $\mathrm{CH}_{4}(1 \%)$ and $\mathrm{C}_{2} \mathrm{H}_{6}(3 \%)$. In the case of $\mathbf{2 b}$ the main product is propene; side products are cyclopropane ( $1 \%$ ) and traces ( $\Sigma 0.4 \%$ ) of $\mathrm{CH}_{4}$, $\mathrm{C}_{2} \mathrm{H}_{6}, \mathrm{C}_{2} \mathrm{H}_{4}$ and $\mathrm{C}_{3} \mathrm{H}_{8}$. In contrast, thermolysis of the analogous cobaloxime $\left[(\mathrm{py})(\mathrm{Hdmg})_{2} \mathrm{Co}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{Co}(\mathrm{Hdmg})_{2}(\mathrm{py})\right](\mathrm{py}=$ pyridine) affords only cyclopropane, ${ }^{20}$ but there are conflicting reports on this complex (see below).

Thermolysis of the butane- and pentane-diyl complexes $2 \mathbf{c}$ and $\mathbf{2 d}$ is less selective. In the case of $\mathbf{2 c}$ the main products are but-1-ene (60), buta-1,3-diene (20) and but-2-ene ( $8 \%$ ) and in the case of $2 \mathbf{d}$ pentenes ( $52 \%$; pent-1-ene:pent-2-ene ca. 2:1) and penta-1,3-dienes ( $40 \%$ ).

The neutral nucleophile $\left[\mathrm{Rh}^{1} \mathrm{~L}^{\prime}\right] \mathbf{A}$ reacts with 1, $\omega$-dihalogeno-

alkanes to give mono- and di-nuclear complexes [ $\mathrm{Rh}^{\text {III }}\left(\mathrm{L}^{\prime}\right) \mathrm{X}-$ $\left.\left\{\left(\mathrm{CH}_{2}\right)_{n} \mathrm{X}^{\prime}\right\}\right]$ and $\left[\mathrm{X}\left(\mathrm{L}^{\prime}\right) \mathrm{Rh}^{\mathrm{II}}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{R} h^{\text {III }}\left(\mathrm{L}^{\prime}\right) \mathrm{X}^{\prime}\right](n=2,3,4,6$ or 10 ), respectively. ${ }^{21}$ On the basis of kinetic studies, the authors assumed a 'not well understood' modest neighboring-group activation of bromine by the rhodium(III) macrocycle in the 2- and 3-bromoalkyl intermediates. Here, the kinetics of the corresponding reactions has not been investigated and qualitatively such effects have not been observed.
Analogous to the dinuclear rhodoximes 2, the oligo-methylene-bridged cobaloximes $\quad\left[(\mathrm{py})(\mathrm{Hdmg})_{2} \mathrm{Co}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{Co}-\right.$ $\left.(\mathrm{Hdmg})_{2}(\mathrm{py})\right]$ were prepared with $n=4-8 .{ }^{22}$ However, there are

Table 3 Selected ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR data $(\delta, \mathrm{J} / \mathrm{Hz})$ for type $\mathbf{1 - 3}$ complexes

conflicting reports on the trimethylene-bridged cobaloxime ( $n=3$ ): the analogous synthesis failed, and attempts were unsuccessful ${ }^{22}$ to prepare this complex as described in the literature. ${ }^{20}$ To date, there have been no reports of the dimethylenebridged cobaloxime ( $n=2$ ).

## NMR spectroscopy

All compounds $\mathbf{1 - 3}$ were characterized by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR spectroscopy (see Table 3). The ${ }^{31} \mathrm{P}$ chemical shifts were found between $\delta 6.5$ and 14.7 in the range expected for organorhodoximes with triphenylphosphine as axial base ${ }^{7 e}$ as is found generally for triphenylphosphine metal complexes. ${ }^{23}$ For the dinuclear ethanediyl (2a) and propanediyl complexes (2b) the ${ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra exhibit typical $\mathrm{AA}^{\prime}$ patterns of $\mathrm{AA}^{\prime} \mathrm{XX}^{\prime}$ systems ( $\mathrm{A}={ }^{31} \mathrm{P}, \mathrm{X}={ }^{103} \mathrm{Rh}$ ). The simulations ${ }^{24}$ of the observed spectra gave considerable ${ }^{5} J\left({ }^{31} \mathrm{P}-{ }^{31} \mathrm{P}\right)$ and ${ }^{6} J\left({ }^{31} \mathrm{P}-{ }^{-31} \mathrm{P}\right)$ couplings ( $36.7,11.2 \mathrm{~Hz}$ ). The long-range $\mathrm{Rh}-\mathrm{P}^{\prime}$ and $\mathrm{Rh}-\mathrm{Rh}$ couplings are much smaller $\left[2 \mathrm{a}, \quad{ }^{4} J\left({ }^{103} \mathrm{Rh}-{ }^{31} \mathrm{P}\right)=4.4\right.$, ${ }^{3} J\left({ }^{103} \mathrm{Rh}-{ }^{103} \mathrm{Rh}\right)<1 ; \mathbf{2 b},{ }^{5} J\left({ }^{103} \mathrm{Rh}-{ }^{31} \mathrm{P}\right)=1.1,{ }^{4} J\left({ }^{103} \mathrm{Rh}-{ }^{-103} \mathrm{Rh}\right)<$ 1 Hz ]. For the homologous butanediyl- (2c) and pentanediylbridged (2d) complexes the corresponding coupling constants [ ${ }^{n} J\left({ }^{31} \mathrm{P}-{ }^{31} \mathrm{P}\right),{ }^{n-1} J\left({ }^{103} \mathrm{Rh}-{ }^{31} \mathrm{P}\right) ; n=7$ or 8$]$ are zero and ${ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of first order were found.
The coupling constants ${ }^{1} J\left({ }^{103} \mathrm{Rh}-{ }^{31} \mathrm{P}\right)$ reflect the trans influence of the organo ligand R. ${ }^{7 e, g-i}$ Their magnitudes between 59.8 and 65.0 Hz for complexes $\mathbf{1}$ and 2 point to a trans influence of $\omega$-halogenoalkyl $\left[\left(\mathrm{CH}_{2}\right)_{n} \mathrm{X}\right]$ and metalloalkyl $\left\{\left(\mathrm{CH}_{2}\right)_{n}[\mathrm{Rh}]\right\}$ ligands that is in the range of those for other alkyl and vinyl ligands ( $49-66 \mathrm{~Hz}$ ), while the more electronegative
alkynyl (ca. 80 Hz ) and halide ligands (113-120 Hz) exhibit greater couplings, consistent with a weaker trans influence

As expected for complexes $1-3$, the chemical shifts $\delta\left({ }^{(3} \mathrm{C}\right)$ of the aryl carbon atoms and the coupling constants ${ }^{n} J\left({ }^{31} \mathrm{P}-{ }^{13} \mathrm{C}\right)$ are in the order $\delta_{o}>\delta_{i}>\delta_{p}>\delta_{m}$ and ${ }^{1} J>{ }^{2} J \approx^{3} J>{ }^{4} J$, respectively. Owing to the non-zero long-range couplings ${ }^{5 / 6} J\left({ }^{31} \mathrm{P}-{ }^{31} \mathrm{P}\right)$, ${ }^{4 / 5} J\left({ }^{103} \mathrm{Rh}^{31} \mathrm{P}\right)$, and ${ }^{3 / 4} J\left({ }^{103} \mathrm{Rh}-{ }^{-103} \mathrm{Rh}\right)$ the carbon atoms $\mathrm{C}_{i}, \mathrm{C}_{o}$ and $\mathrm{C}_{m}$ of $\mathbf{2 a}$ and $\mathbf{2 b}$ exhibit A parts of $\mathrm{AMM}^{\prime} \mathrm{XX}^{\prime}$ systems ( $\mathrm{A}={ }^{13} \mathrm{C}, \mathrm{M}={ }^{31} \mathrm{P}, \mathrm{X}={ }^{103} \mathrm{R} \mathrm{h}$ ) which could be simulated using the magnitudes of the coupling constants obtained from the ${ }^{31}$ P NMR spectra (see Table 3 for $\mathrm{C}_{i}$ ).

For the $\omega$-halogenoalkyl complexes $\mathbf{1 b}$ and $\mathbf{1 d}$ the order of magnitude ${ }^{2} J \gtrdot{ }^{4} J>{ }^{3} J \S$ of the coupling constants ${ }^{n} J\left({ }^{31} \mathrm{P}-{ }^{13} \mathrm{C}\right)$ was found. Furthermore, ${ }^{1} J\left({ }^{103} \mathrm{Rh}-{ }^{13} \mathrm{C}\right) \gg{ }^{3} J\left({ }^{103} \mathrm{R} h^{-13} \mathrm{C}\right)$ and ${ }^{2} J\left({ }^{103} \mathrm{Rh}-{ }^{-13} \mathrm{C}\right) \approx 0$.

As a consequence of the long-range couplings between P and $\mathrm{P}^{\prime}, \mathrm{Rh}$ and $\mathrm{Rh}^{\prime}$, and Rh and $\mathrm{P}^{\prime}$, the resonances of the $\alpha-\mathrm{C}$ atoms in the ethanediyl and propanediyl bridges of complexes $\mathbf{2 a}$ and $\mathbf{2 b}$ appear as the A parts of $\mathrm{AMM}^{\prime} \mathrm{XX}^{\prime}$ systems ( $\mathrm{A}={ }^{13} \mathrm{C}, \mathrm{M}={ }^{31} \mathrm{P}, \mathrm{X}={ }^{103} \mathrm{Rh}$ ). The experimental and simulated spectra for $\mathbf{2 b}$ are shown in Fig. 1. In the case of the spin system of complex 2a, a good correspondence between experimental and simulated spectra requires that at least one of the three long-range couplings has a negative sign. The central $\beta$-C atom of complex $\mathbf{2 b}$ and all bridging carbon atoms of $\mathbf{2 c}$ and $\mathbf{2 d}$ exhibit first-order spectra.

[^1]

Fig. 1 Experimental (below) and simulated (above) ${ }^{13} \mathrm{C}$ NMR spectra of the $\alpha-\mathrm{C}$ atom in complex $\mathbf{2 b}$. The coupling constants ${ }^{1} J\left(\mathrm{Rh}^{1}-\mathrm{P}\right)=$ $61.8,{ }^{4} J(\mathrm{Rh}-\mathrm{Rh})<1,{ }^{5} J(\mathrm{Rh}-\mathrm{P})=1.1$ and ${ }^{6} J(\mathrm{P}-\mathrm{P})=11.2 \mathrm{~Hz}$ were taken from the ${ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ spectrum (see text and Table 3). The calculated coupling constants are as follows: ${ }^{1} J(\mathrm{Rh}-\mathrm{C})=19.4,{ }^{2} J(\mathrm{P}-\mathrm{C})=72.0$, ${ }^{3} J(\mathrm{Rh}-\mathrm{C})=2.6,{ }^{4} J(\mathrm{P}-\mathrm{C})=12.7$ and ${ }^{5} J(\mathrm{Rh}-\mathrm{P})=2.6 / 3.0 \mathrm{~Hz}$

Owing to the formation of rhodacycles, all carbon atoms in complexes 3 are chemically inequivalent. Thus, the equatorial pseudo-macrocyclic ligand exhibits four signals for the $\mathrm{C}=\mathrm{N}$ carbon atoms and four signals for the methyl carbon atoms (Table 3). In complexes $\mathbf{3 b}$ and $\mathbf{3 c}$ the carbon and proton resonances of the methyl groups were assigned on the basis of heteronuclear correlation (HETCOR) experiments.

In complexes 3 the carbon atoms attached to oxygen are shifted strongly downfield (73-79 ppm). All protons of the methylene groups $\left(\mathrm{CH}_{2}\right)_{n}$ are chemically inequivalent and all geminal protons are well separated. Shift differences between geminal protons were found up to $1.26 \mathrm{ppm}\left(\gamma-\mathrm{CH}_{2}\right.$ in $\left.\mathbf{3 b}\right)$ corresponding to 630 Hz at 500 MHz . Thus, the proton resonances of the $\left(\mathrm{CH}_{2}\right)_{n}$ groups appear as first-order multiplets in most cases.

## Molecular structures

$[\mathbf{R h}]\left(\mathbf{C H}_{2}\right)_{n}[\mathbf{R h}](n=\mathbf{2} \mathbf{2 a}, \mathbf{3} \mathbf{2 b}$ or $\mathbf{4 2 c})$. All complexes crystallize with discrete molecules without any remarkable intermolecular interactions. The molecular structures are shown in Figs. 2-4. Selected bond lengths and angles are listed in Tables 4-6. Complexes 2a and 2c have crystallographically imposed inversion symmetry.

The Rh atoms display a distorted octahedral co-ordination, with the two dimethylglyoximate ligands in the equatorial plane and $\mathrm{PPh}_{3}$ and the alkanediyl ligand in the axial positions. As in other rhodoximes, ${ }^{7,10,11}$ the two $\mathrm{Hdmg}^{-}$ligands are stabilized by two strong intramolecular $\mathrm{O}-\mathrm{H}-\mathrm{O}$ hydrogen bonds $[\mathrm{O} \cdots \mathrm{O}$ : 2a, 2.694(4), 2.731(4); 2b, 2.605(4)-2.782(4); 2c, 2.694(8), $2.748(9) \AA$ ㄱ.

The $\mathrm{P}-\mathrm{Rh}-\mathrm{C}$ units are nearly linear (see Table 7). The Rh-P bond lengths [2a, 2.4755(9); 2b, $\quad \mathrm{Rh}(1)-\mathrm{P}(1) \quad 2.489(1)$,
$\mathrm{Rh}(2)-\mathrm{P}(2)$ 2.479(1); 2c, $\mathrm{Rh}-\mathrm{P} 2.484(2) \AA$ ] are in the range of those of analogous mononuclear alkylrhodoximes $\{[R h]-R$, $\mathrm{R}=\mathrm{Me}, \mathrm{Et}, \mathrm{Pr}^{\mathrm{i}}$ or $\left.\mathrm{Bu}^{\mathrm{t}} ; \mathrm{Rh}-\mathrm{P} 2.454(1)-2.492(1) \AA^{10 a, d-f}\right\}$. In the same way, the $\mathrm{Rh}-\mathrm{C}$ bond lengths [2a, $\mathrm{Rh}-\mathrm{C}(27 \mathrm{~A}) 2.17(1)$, $\mathrm{Rh}-\mathrm{C}(27 \mathrm{~B}) 2.15(2) ; 2 \mathrm{~b}, \mathrm{Rh}(1)-\mathrm{C}(53) 2.118(3), \mathrm{Rh}(2)-\mathrm{C}(55)$ $2.120(3) ; 2 \mathrm{c}, \mathrm{Rh}-\mathrm{C}(27) 2.117(7) \AA$ ] correspond to those in the mononuclear alkyl complexes $[\mathrm{Rh}]-\mathrm{R}\left[\mathrm{R}=\mathrm{Me}, \mathrm{Et}, \mathrm{Pr}^{\mathrm{i}}\right.$ or $\mathrm{Bu}^{\mathrm{t}}$; $\left.\mathrm{Rh}-\mathrm{C} 2.064(7)-2.216(3) \AA^{10 a, d-f}\right]$. The two $\mathrm{Hdmg}^{-}$ligands are tilted away from the triphenylphosphine ligand as described by the angle $(\alpha)^{25}$ between the normals to the Hdmg planes and by the displacement of the Rh atom out of the mean plane passing through the four oxime N -donor atoms toward the P atom $\left[d\left(\mathrm{Rh} / \mathrm{N}_{4}\right)\right]$, ${ }^{25}$ see Table 7. Similar values for $\alpha$ and $d$ were found in mononuclear alkylrhodoximes (Table 7).

In complex $\mathbf{2 b}$ the torsion angles $\mathrm{Rh}(1)-\mathrm{C}(53)-\mathrm{C}(54)-\mathrm{C}(55)$ [179.2(3)] and $\mathrm{C}(53)-\mathrm{C}(54)-\mathrm{C}(55)-\mathrm{Rh}(2)\left[174.5(3)^{\circ}\right]$ reveal that the conformation of the $\mathrm{RhCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Rh}$ chain is fully staggered ( $a p$ ). Thus, both disc-like $\mathrm{Rh}(\mathrm{Hdmg})_{2}$ moieties take up the greatest distance from each other. The tilt angle between the two $\mathrm{N}_{4}$ planes is $45.0(1)^{\circ}$. These two planes exhibit a nearly perfectly staggered conformation [mean of the torsion angles $\mathrm{N}-\mathrm{Rh}(1)-\mathrm{Rh}(2)-\mathrm{N}$ is $90.6^{\circ}$, which obviously minimizes the electrostatic repulsion between the $\mathrm{O}-\mathrm{H}-\mathrm{O}$ moieties and the steric interference between two methyl groups. The closest contacts between the two equatorial ligands $[\mathrm{O}(1) \cdots \mathrm{C}(16)$ $3.485(6) ; \mathrm{O}(8) \cdots \mathrm{C}(1) 3.513(6) \AA$ ] correspond with the sum of van der Waals radii $(3.50 \AA$ ) for a methyl group $\left[r_{\text {vdw }}\left(\mathrm{CH}_{3}\right)=2.00 \AA^{26}\right]$ and an oxygen atom $\left[r_{\mathrm{vdw}}(\mathrm{O})=1.50 \AA\right] .^{26}$ The dimeric rhodium(II) complex [Rh]-[Rh] with its $\mathrm{Rh}-\mathrm{Rh}$ single bond also exhibits a staggered conformation of the two $(\mathrm{Hdmg})_{2}$ ligands (deviation of the ideal conformation: $3.0^{\circ}$ ) with $\mathrm{Me} \cdots \mathrm{O}$ distances of $3.37 \AA$ (mean value). ${ }^{27}$

The relatively large angles $[\mathrm{Rh}(1)-\mathrm{C}(53)-\mathrm{C}(54)$ 119.3(2), $\left.\mathrm{Rh}(2)-\mathrm{C}(55)-\mathrm{C}(54) 118.3(2)^{\circ}\right]$ seem not to be a consequence of the steric interference of the two $(\mathrm{Hdmg})_{2}$ moieties. Similar values were found in complex $2 \mathrm{c}\left[\mathrm{Rh}-\mathrm{C}(27)-\mathrm{C}(28) 119.9(5)^{\circ}\right]$ and in the mononuclear rhodoximes $[\mathrm{Rh}]-\mathrm{R}\left[\mathrm{R}=\mathrm{Et}\right.$ or $\mathrm{Pr}^{\mathrm{i}}$ : 116.2(5)-119.3(6) $\left.{ }^{\circ 10 a, e}\right]$.

As in complex $\mathbf{2 b}$, the conformations of the chains $\mathrm{RhCH}_{2}-$ $\mathrm{CH}_{2} \mathrm{Rh}$ in 2a and $\mathrm{RhCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Rh}$ in 2c are fully staggered (ap) [torsion angles: 2a, $\mathrm{Rh}-\mathrm{C}(27)-\mathrm{C}\left(27^{\prime}\right)-\mathrm{Rh} 180$; 2c, $\mathrm{Rh}-\mathrm{C}(27)-\mathrm{C}(28)-\mathrm{C}\left(28^{\prime}\right) 177.1(7)^{\circ}, \mathrm{C}(27)-\mathrm{C}(28)-\mathrm{C}\left(28^{\prime}\right)-$ $\left.\mathrm{C}\left(27^{\prime}\right) 180^{\circ}\right]$. As a consequence of the inversion centres, the two $\mathrm{N}_{4}$ planes are parallel in 2a and $\mathbf{2 c}$ with distances of $4.5(\mathbf{2 a})$ and $7.1 \AA(\mathbf{2 c})$. Furthermore, the two $\mathrm{RhN}_{4}$ units in $\mathbf{2 a}$ and in $\mathbf{2 c}$ exhibit a perfectly ecliptic conformation, contrary to the staggered conformation in $\mathbf{2 b}$.

Cyclic organorhodoxime 3b. Complex 3b crystallizes with discrete molecules, see Fig. 5. Selected bond lengths and angles are listed in Table 8. The distortion of the co-ordination polyhedron $\mathrm{RhN}_{4} \mathrm{PC}$ is similar to those of the dinuclear complexes 2 and other organorhodoximes (Table 7).

The six-membered ring (1-oxa-2-aza-3-rhodacyclohexane) exhibits a distorted chair conformation with angles between $79.7(3)[\mathrm{C}(27)-\mathrm{Rh}-\mathrm{N}(1)]$ and $123.2(5)^{\circ}[\mathrm{Rh}-\mathrm{N}(1)-\mathrm{O}(1)]$ and torsion angles (absolute values) between 53.4(7) and 74.9(8) ${ }^{\circ}$. The relatively small angle $\mathrm{C}(27)-\mathrm{Rh}-\mathrm{N}(1)\left[79.7(3)^{\circ}\right]$ compared with the other $\mathrm{C}-\mathrm{Rh}-\mathrm{N}$ angles $\left[88.0(3)-91.7(3)^{\circ}\right]$ might be indicative of a degree of strain in the ring as is the relatively large angle $\mathrm{P}-\mathrm{Rh}-\mathrm{N}(1)$ [97.4(2) ${ }^{\circ}$ ] compared with the other $\mathrm{P}-\mathrm{Rh}-\mathrm{N}$ angles $\left[87.0(2)-94.0(2)^{\circ}\right.$ ].

The $\mathrm{N}(1)-\mathrm{O}(1)$ bond $[1.424(9) \AA]$ is significantly longer than the other $\mathrm{N}-\mathrm{O}$ bonds $[1.303(9)-1.380(9) \AA]$. In marked contrast to the $\mathrm{O}(2)-\mathrm{H}(3)-\mathrm{O}(3)$ unit $[\mathrm{O}(2) \cdots \mathrm{O}(3) 2.58(1) \AA$, the distance between the oxygen atoms that are not connected via a hydrogen bridge is distinctly longer $[\mathrm{O}(1) \cdots \mathrm{O}(4) 3.30(1) \AA]$. Correspondingly, the angle $\mathrm{N}(1)-\mathrm{Rh}-\mathrm{N}(4)[108.8(3) \AA]$ is larger than $\mathrm{N}(2)-\mathrm{Rh}-\mathrm{N}(3) 98.1(3) \AA$.

To summarize, the reactions of $[\mathrm{Rh}]^{-}$with $\mathrm{X}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{X}^{\prime}(n=$

Symmetry transformation ('): $-x+1,-y+1,-z+1 . * \sigma_{n-1}$ in parentheses; minimum and maximum values in square brackets.

2-5) afford in the first step $\omega$-halogenoalkyl rhodoximes $\mathbf{1}$ that can react further (i) with $[\mathrm{Rh}]^{-}$in an intermolecular reaction to give dinuclear oligo-methylene-bridged rhodoximes 2, (ii) in an intramolecular substitution reaction to give cyclic organorhodoximes 3 ( $n=3-5$ ) or (iii) in a heterolytic fragmentation reaction with splitting off of ethylene ( $n=2$ ). The fully stag-
gered conformation (ap) of the $\mathrm{Rh}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{Rh}$ chains ( $n=2-4$ ) sufficiently prevents steric interference between the bulky disclike pseudo-macrocyclic (Hdmg) ${ }_{2}$ ligands, even in the propanediyl complex 2b. (Difficulties in preparing the corresponding organocobaloxime were attributed to steric factors. ${ }^{22}$ ) These investigations contribute to the understanding of the stability

Fig. 2 Molecular structure and numbering scheme of complex $\mathbf{2 a}$ [only split position $\mathrm{C}(27 \mathrm{~A})$ is shown]. Ellipsoids are drawn at the $30 \%$ probability level. Apart from the $\mathrm{O}-\mathrm{H}-\mathrm{O}$ bridges, hydrogen atoms have been omitted for clarity. For the same reason, phenyl carbons were not included in the numbering scheme

Fig. 5 Molecular structure and numbering scheme of complex 3b. Details as in Fig. 2
and reactivity of oligo-methylene-bridged rhodoximes and reveal a novel pathway for an interligand reaction between an axial functionalized organo ligand and an equatorial oximato/ oxime ligand.

## Acknowledgements

We thank the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie for financial support and the companies Merck (Darmstadt) and Degussa (Hanau) for loans of chemicals. Dr. G. Ohms, University of Dresden, is acknowledged for performing the ${ }^{13} \mathrm{C}-\left\{{ }^{31} \mathrm{P}\right\}$ decoupling experiments.

Received 26th August 1997; Paper 7/06184F

[^0]:    $\dagger$ E-Mail: steinborn@chemie.uni-halle.de
    $\ddagger$ Abbreviations: $\quad[\mathrm{Rh}]=\left[\mathrm{Rh}(\mathrm{Hdmg})_{2}\left(\mathrm{PPh}_{3}\right)\right], \quad \mathrm{H}_{2} \mathrm{dmg}=$ dimethylglyoxime, R = hydrocarbyl ligand.

[^1]:    § The assignments of the carbon atoms were verified by $\mathrm{H}-\mathrm{C}$ correlation spectroscopy (COSY). In the literature ${ }^{7 e} \delta\left({ }^{13} \mathrm{C}\right)$ of the $\beta$ - and $\gamma$-carbon atoms in [ Rh$]-\mathrm{R}(\mathrm{R}=$ alkyl $)$ were exchanged erroneously.
