(Received 14 January 1993; accepted 13 May 1993)

#### Abstract

Two series of potentially cross-linkable liquid crystal materials derived from $p$ phenylenebisacrylic (series I, $n($ P.FB.P), $n=2-10$ ) and $p$-hydroxycinnamic acid (series II, $n($ HC.T.HC $), n=2-10$ ) have been synthesized and their thermal and mesomorphic properties studied. All these compounds show enantiotropic mesomorphism over a wide range of temperatures. Compounds with short terminal chains are nematic and when the terminal chain length is increased they show smectic polymorphism-smectic A and C. Most of the compounds are thermally stable over their mesophase ranges.

## 1. Introduction

The photoreaction process in liquid crystals has been a subject of research over the last few years. Different objectives can be achieved using this method: anisotropic calamitic and discotic networks [1-4], main chain and side chain cross-linked polymers [5-9], elastomers [10-12], topochemical reactions [13], generation of phase transitions [14], reversible optical effects [15-17], etc. The cinnamoyl group has often been used as a reactive unit included in mesogenic molecules [4,5,10,13], even in basic studies of liquid crystal photoreactions [18, 19]. In this field our group is interested in the synthesis of self-reinforced polymers as engineering materials. For this purpose we use complex monomers including the cinnamoyl group in different positions [20-23]. In some cases we use low molecular weight compounds.

This paper deals with the synthesis and characterization of two series of potentially photopolymerizable mesogenic compounds, whose basic structure is centro-symmetric with cinnamoyl moieties as photoreactive groups. The double bonds in series I come from $p$-phenylenebisacrylic acid, so that the reactive groups are very close to the molecular centre. The double bonds in series II bonds come from $p$-hydroxycinnamic acid and are located in the external part of the mesogenic core.

Series I, $n$ (P.FB.P), $n=2-10$
*Author for correspondence.

These compounds are to be studied with reference to their thermal stability and mesomorphic properties, in order to determine the influence of the position of the double bonds on the mesomorphic ordering. This study will enable us to choose the most interesting candidates for further studies of liquid crystal photoreactions.

## 2. Experimental

2.1. Synthesis

### 2.1.1. Synthesis of diacids

2.1.1.1. 4,4'-p-(Phenylenediacryloxyloxy)dibenzoic acid (P.FB.P diacid)

To a solution of $28.2 \mathrm{~g}(0 \cdot 2 \mathrm{~mol})$ of $p$-hydroxybenzoic acid in 200 ml of 2 M NaOH , vigorously stirred, a solution of $25.5 \mathrm{~g}(0.1 \mathrm{~mol})$ of $p$-phenylenediacryloyl chloride in 180 ml of 1,4 -dioxan was added all at once. After stirring for 1 h , the white precipitate was collected, washed with water, 1 M HCl and then acetone, and vacuum dried to yield 42 g ( 85 per cent) of $4,4^{\prime}$-( $p$-phenylenediacryloyloxy)dibenzoic acid.

### 2.1.1.2. 4,4'-(Terephthaloyldioxy)dicinnamic acid (HC.T.HC diacid)

To a solution of $32.4 \mathrm{~g}(0.2 \mathrm{~mol})$ of $p$-hydroxycinnamic acid, a solution of 20.3 g $(0.1 \mathrm{~mol})$ of terphethaloyl chloride was added all at once. After stirring for 1 h , the white precipitate was collected, washed with water, 1 M HCl and then acetone, and vacuum dried to yield $34 \cdot 6 \mathrm{~g}$ ( 70 per cent) of $4,4^{\prime}$-(terephthaloyldioxy)dicinnamic acid.

### 2.1.2. Synthesis of diacid chlorides

P.FB.P and HC.T.HC diacids were heated under refiux with thionyl chloride and a catalytic amount of pyridine for 5 h . The solids were filtered off from hot mixtures and recrystallized from toluene to yield $4,4^{\prime}$-( $p$-phenylenediacryloyloxy)dibenzoyl chloride (DC.P.FB.P) ( 55 per cent) and 4,4'-(terephthaloyldioxy)dicinnamoyl chloride (DC.HC.T.HC) (50 per cent).

### 2.1.3. Synthesis of diester derivatives

Two different methods were used to obtain the diester derivatives dependent upon their terminal chain length. The syntheses are described in general form below.

## Method 1

A solution of 2 mmol of DC.P.FB.P or DC.HC.T.HC in 50 ml of 1,4-dioxan, 25 ml of pyridine and 25 ml of the aliphatic alcohol was heated with stirring at $100^{\circ} \mathrm{C}$ for 3 h . The cooled solution was poured into hexane. The white precipitate was collected and purified.

## Method 2

A 5 mmol mixture of DC.P.FB.P or DC.HC.T.HC and 15 mmol of the aliphatic alcohol in 15 ml of diphenyl ether was introduced into a condensation tube and dry

[^0]nitrogen was bubbled through at room temperature for 30 min . The mixture was then heated to 150 or $200^{\circ} \mathrm{C}$ (see table 1) for 30 min . Toluene (P.FB.P series) or hexane (HC.T.HC series) was used as precipitant. The white solids were collected and purified.

The crude diesters were purified by recrystallization from toluene and column chromatography on silica gel using dichloromethane as eluent; then they were recrystallized again. $n$ (P.FB.P) compounds and 2(HC.T.HC) were recrystallized from toluene and the $n$ (HC.T.HC) compounds from toluene/hexane.

The method of synthesis used in each case ( 1 or 2 ), the reaction temperature and the yield after purification of the $n$ (P.FB.P) and $n$ (HC.T.HC) diesters are given in table 1.

### 2.2. Characterization of the compounds

All the compounds were characterized by elemental analysis and FTIR spectroscopy. In table 1 reaction data, elemental analysis results and fundamental IR bands, corresponding to $\mathrm{C}=\mathrm{O}$ bonds (stretching) $\mathrm{C}=\mathrm{C}$ bonds (stretching), and $\mathrm{C}-\mathrm{H}$ (bending) for the diester derivatives are gathered.

Due to the fact that the UV-visible and the ${ }^{1} \mathrm{H}$ and 13C NMR spectra of analogous compounds within each series are very similar, we have included spectroscopic data only for the octyl derivatives, as representative examples (see table 2). All the results in tables 1 and 2 are in good agreement with the proposed structures.

### 2.3. Techniques

FTIR spectra were recorded using a Perkin-Elmer 1725X spectrometer, and elemental analyses were carried out with a Perkin-Elmer 240C microanalyser. UV-vis spectra were recorded using a Milton Roy Spectronic 3000 Array and dichloromethane solutions. ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ NMR spectra were obtained with a Varian XL-200 instrument using $\mathrm{CDCI}_{3}$ solutions.

Transition characteristics and mesophase textures of the diesters were studied by means of a Reichert-Jung Thermogalen HT 240 polarizing microscope with a heating stage and a temperature control unit.

DSC measurements were performed with a Perkin-Elmer DSC-7 at a heating rate of $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$ under nitrogen. The apparatus was calibrated with indium (m.p. $156.6^{\circ} \mathrm{C}$, heat of fusion $28.42 \mathrm{Jg} \mathrm{g}^{-1}$ ) and tin (m.p. $231 \cdot 9^{\circ} \mathrm{C}$, heat of fusion $60.40 \mathrm{~J} \mathrm{~g}^{-1}$ ). Transition temperatures were read at the peak onsets. Thermogravimetric analyses were carried out using a Perkin-Elmer TGA-7 at $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$ under nitrogen.

## 3. Results and discussion

### 3.1. Synthesis

We have synthesized the P.FB.P and HC.T.HC diacids in a single step reaction, avoiding protection and deprotection procedures for the functional groups. The synthesis of these compounds has been published using the interfacial condensation method [20,22]. In this work we have modified this method, replacing chloroform with 1,4-dioxan for the diacid chloride solutions in order to avoid chloroform/water mixtures which complicate and prolong precipitate processing.

The high temperature diacid chloride-aliphatic alcohol condensation reaction in solvents with high boiling point [29] was a suitable method for preparing the diesters when using aliphatic alcohols with more than four carbon atoms. The temperature of
the original synthesis $\left(200^{\circ} \mathrm{C}\right)$ was decreased (to $150^{\circ} \mathrm{C}$ ) for $n$-butanol in the P.FB.P series, and $n$-pentanol and $n$-hexanol in the HC.T.HC series in order to avoid evaporation of aliphatic alcohol before reaction.

Using ethanol, $n$-propanol and $n$-butanol in this method for the P.FB.P series was not successful even at low temperatures $\left(150^{\circ} \mathrm{C}\right)$. For this reason we tried out various solvents and chose condensation Method 1, using 1,4-dioxan/pyridine [22] at $100^{\circ} \mathrm{C}$.

### 3.2. Structural characterization

Spectroscopic data made it possible to obtain some structural information about the compounds, for example, the ${ }^{1} \mathrm{H}$ NMR spectra and the IR wave number of the -C-H vibration confirm the E-conformation of the double bond in both structures (coupling constant 16 Hz and IR wavenumber of the $=\mathrm{C}-\mathrm{H}$ vibration $970-980 \mathrm{~cm}^{-1}$ ).

In some cases, the IR spectroscopic data show more than two carbonyl bands4(HC.T.HC) and 5(HC.T.HC). This behaviour may be due to the fact that the HC.T.HC unit might exit in the s-cis- and s-trans-conformations simultaneously. On the other hand, the rest of the compounds show only two carbonyl bands, probably due to the energetically more favourable s-cis-conformation (see figure 1) in accordance with MNDO calculations [24] and X-ray crystallographic data [25, 26].

The UV-visible spectra of the homologous compounds of the series synthesized are very different. The $p$-phenylenebisacrylic acid derivatives (series I) show a bathochromic shift and a hyperchromic effect in relation to the $p$-hydroxycinnamic acid derivatives (series II) (see figure 2). These results indicate a major extension of conjugation in the first case and probably a more planar structure. These results could suggest greater intermolecular interactions for the $n$ (P.FB.P) diesters compared to the $n$ (HC.T.HC) diesters and explain the higher melting points for the former series.

Figure 1. Most stable conformations of the two mesogenic units in series I and series II.

Figure 2. UV-visible spectra of octyloxycarbonyl derivatives in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ : 8(P.FB.P), $c=1.8 \times 10^{-5} \mathrm{M}(-) ; 8($ HC.T.HC $), c=2.0 \times 10^{-5} \mathrm{M}(-\cdots)$.

### 3.3. Thermal and mesomorphic behaviour

All the compounds show mesomorphic behaviour. The type of mesophase, transition temperatures and enthalpy values for the different transitions for series I ( $n($ P.FB.P $)$ ) and series II ( $n($ HC.T.HC $)$ ) are summarized in tables 3 and 4 , respectively.

In spite of their high clearing temperatures, most of the diesters were thermally stable during the DSC measurements over the temperature ranges scanned (from $20^{\circ} \mathrm{C}$ to $30^{\circ} \mathrm{C}$ after their clearing points). For this reason, the data gathered in tables 3 and 4 correspond to the second heating scan. Only 2(P.FB.P), 3(P.FB.P) and 2(HC.T.HC) decompose partially in the isotropic state, and the DSC data for these materials correspond to the first heating scan.

Thermogravimetric studies of the octyloxycarbonyl derivatives were carried out under a nitrogen atmosphere with a heating rate of $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$. The onset values of the decomposition curves (TG curves) are $368^{\circ} \mathrm{C}$ for series I and $387^{\circ} \mathrm{C}$ for series II. The peaks of the first TG derivative are at $391^{\circ} \mathrm{C}$ for 8 (P.FB.P) and $410^{\circ} \mathrm{C}$ for 8 (HC.T.HC). Weight loss is not detected at lower temperatures. Most of the synthesized diesters exhibit crystalline polmorphism, which was detected by DSC. In many cases these transitions are reproducible (tables 3 and 4).

The compounds in series I and series II show the typical mesomorphic behaviour of calamitic liquid crystals: nematic for the members with shorter terminal chains and smectic when the terminal chain length is increased [30]. The odd-even effect is observed for the nematic-isotropic transitions (see figures 3 and 4). Both series show smectic polymorphism-smectic A and C.

The nematic mesophase was identified by its characteristic marbled texture. It is noted that the nematic mesophase exhibits large homeotropic areas on heating and cooling. The $\mathrm{S}_{\mathrm{A}}$ mesophase shows homeotropic and focalconic textures on heating and

Transition temperatures as a function of alkyl chain length for the $n($ P.FB.P) (series I): $\mathrm{C}-\mathrm{S}_{\mathrm{C}}(\oplus) ; \mathrm{C}-\mathrm{S}_{\mathrm{A}}(\boxtimes) ; \mathrm{C}-\mathrm{N}(\stackrel{\rightharpoonup}{4}) ; \mathrm{S}_{\mathrm{C}}-\mathrm{S}_{\mathrm{A}}(\nabla) ; \mathrm{S}_{\mathrm{A}}-\mathrm{N}(\bullet) ; \mathrm{S}_{\mathrm{A}}-\mathrm{I}(\mathbb{\Sigma}) ; \mathrm{N}-\mathrm{I}(\bullet)$.

Figure 4. Transition temperatures as function of alkyl chain length for the $n$ (HC.T.HC) (series

cooling. The $\mathrm{S}_{\mathrm{C}}$ mesophases were clearly identified on cooling by their broken focalconic texture, if this came from a similar $S_{A}$ texture or by their schlieren texture when this came from a homeotropic texture of this proceeding phase.

The $4,4^{\prime}$-(terephathaloyl)dicinnamoyl and $4,4^{\prime}$-phenylenediacryloyloxydibenzoyl moieties show a high mesogenic capability, for the diester derivatives of both series exhibit wide range enantiotropic mesomorphism which must be due to their structural characteristics. The most likely conformations (s-cis and s-trans-, see figure 1) enable high electronic conjugation and are planar, both vary favourable for mesomorphism.

Homologous compounds within each series show similar isotropic transition temperatures. The compounds in series II exhibit lower melting temperatures than the compounds in series I, so, that the $p$-hydroxycinnamic acid derivatives show wider enatiotropic mesomorphic ranges. The UV-vis data indicate that the electronic conjugation and therefore the planarity for the $n$ (P.FB.P) molecules are greater than that for the homologous $n$ (HC.T.HC) compounds. This could explain the higher melting temperatures of the compounds in the former series-see tables 3 and 4.

## 4. Conclusions

All the compounds in the two series exhibit wide range mesomorphism, homolog. ous compounds of both series having very similar clearing points. On the other hand, the melting points are significantly different. These results could be due to structural factors. The position of the double bond, inside (series I) or outside (series II) the central core has a decisive influence.

Most of the compounds exhibit thermally stable mesophases. It is therefore possible to choose homologous compounds from both series as candidates for photopolymerization studies to be effected using different mesophases ( $\mathrm{N}, \mathrm{S}_{\mathrm{A}}, \mathrm{S}_{\mathrm{C}}$ ) and at different temperatures.

Financial support by the C.D.T.I. (Proyect 900074 ), C.I.C.Y.T. (Projer MAT $91-$ 0962-C02-01) and the M.I.C.T. (Project 255/90) are gratefully acknowledged.
