Calculations of Integrals of Products of Bessel Functions

By J. E. Kilpatrick,¹ Shigetoshi Katsura² and Yuji Inoue³

I. Introduction. Integrals of products of Bessel functions are of general interest. Define *W*-integrals by

$$W^{\lambda}_{\nu_{1}\nu_{2}\cdots\nu_{l}}(a_{1}, a_{2}\cdots a_{l}) \\ \equiv \int_{0}^{\infty} J_{\nu_{1}}(a_{1}t) J_{\nu_{2}}(a_{2}t) \cdots J_{\nu_{l}}(a_{l}t) t^{-\lambda} dt$$

In this note we consider

(1.1)
$$W_{3/2+n_1,3/2+n_2,3/2+n_3,3/2+n_4}^4(1,1,1,1) \equiv U_1,$$

where n_1 , n_2 , n_3 , n_4 are zero or positive integers and $n_1 + n_2 + n_3 + n_4$ is even, and

(1.2)
$$W_{3/2+n_1,3/2+n_2,3/2+n_3}^{5/2}(a,b,b) \equiv U_2,$$

where n_1 , n_2 , n_3 are zero or positive integers, $n_1 + n_2 + n_3$ is even and a, b are real positive numbers. The symbols U_i are used for convenient reference.

Integrals (1.1) and (1.2) together with integrals of threefold and fourfold products of associated Legendre functions [7], were used in the calculation of virial coefficients in statistical mechanics [3], [4], [5], [6].

The usual numerical integration techniques such as Simpson's method, Gauss' method, method of indefinite integral of polynomials [7] etc., when applied to integrals with oscillating integrands such as in (1.1) and (1.2) are inefficient.

Values of integrals (1.1) and (1.2) can be obtained by transforming them into Mellin-Barnes integrals [1], [2], etc., or Meijer's *G*-functions [2], and application of the residue calculus as developed by one of the authors in [3] leads to the exact determination of the integrals.

As the Mellin-Barnes integrands are rather complicated, one has to do considerable scanning to determine the actual poles. In this paper, the scanning process and the evaluation of the residues at these poles is computer programmed.

II. $W_{3/2+n_1,3/2+n_2,3/2+n_3,3/2+n_4}^4$ (1, 1, 1, 1). We consider the integral (1.1). We use a series representation of the products of the two Bessel functions [9]:

$$J_{3/2+n_{1}}(t)J_{3/2+n_{2}}(t) = \sum_{s=0}^{\infty} \frac{(-)^{s} \left(\frac{1}{2}t\right)^{3/2+n_{1}+3/2+n_{2}+2s}}{\Gamma\left(\frac{3}{2}+n_{1}+\frac{3}{2}+n_{2}+2s+1\right)} \\ \frac{(2.1)}{s!\Gamma\left(\frac{3}{2}+n_{1}+s+1\right)\Gamma\left(\frac{3}{2}+n_{2}+s+1\right)\Gamma\left(\frac{3}{2}+n_{1}+\frac{3}{2}+n_{2}+s+1\right)}{\frac{1}{\sqrt{\pi}}\sum_{s=0}^{\infty} \frac{(-)^{stn_{1}+n_{2}+3+2s}\Gamma\left(s+\frac{n_{1}+n_{2}+4}{2}\right)\Gamma\left(s+\frac{n_{1}+n_{2}+5}{2}\right)}{s!\Gamma\left(s+n_{1}+\frac{5}{2}\right)\Gamma\left(s+n_{2}+\frac{3}{2}\right)\Gamma\left(s+n_{1}+n_{2}+4\right)} \\ = U_{3}.$$

The summation over s is replaced by a complex integral over ds by using the fact that the residue of $\Gamma(z)$ at z = -l is $(-)^{l}/l!$ for a zero or positive integral value of l. Hence

(2.3)
$$U_{3} = \frac{1}{\sqrt{\pi}} \frac{1}{2\pi i} \int_{s_{0}-i\infty}^{s_{0}+i\infty} \frac{\Gamma(-s+A)\Gamma(s+E)\Gamma(s+F)t^{n_{1}+n_{2}+2s+3}}{\Gamma(s+L)\Gamma(s+J)\Gamma(s+K)},$$

where

(2.4)
$$A = 0, \qquad L = n_1 + 5/2, \qquad E = (n_1 + n_2 + 4)/2, \qquad J = n_2 + 5/2, F = (n_1 + n_2 + 5)/2, \qquad K = n_1 + n_2 + 4,$$

where s_0 is chosen in such a way that the poles of $\Gamma(-s + A)$ lie on the right of the path and the poles of $\Gamma(s + E)$ and $\Gamma(s + F)$ on the left of the path.

From (2.4) -F < -E, thus

(2.5)
$$-E < s_0 < A$$
.

Substituting (2.3) into (1.1), we have

(2.6)
$$U_{1} = \frac{1}{\sqrt{\pi}} \int_{0}^{\infty} dt \frac{1}{2\pi i} \int_{s_{0}-i\infty}^{s_{0}+i\infty} \frac{\Gamma(-s+A)\Gamma(s+E)\Gamma(s+F)}{\Gamma(s+L)\Gamma(s+J)\Gamma(s+K)} \times J_{3/2+n_{s}}(t) J_{3/2+n_{s}}(t) t^{n_{1}+n_{2}+2s+3} ds \equiv U_{4}.$$

Next, s_0 is moved to the left in such a way that the condition for the convergence of Weber-Schafheitlin's integral [9], [2]

(2.7)
$$\int_0^\infty J_{3/2+n_*}(t) J_{3/2+n_*}(t) t^{-1+n_1+n_2+2s} dt$$

is satisfied, if necessary. That is, s_0 is chosen to satisfy simultaneously (2.5) and

(2.8)
$$-D < s_0 < B$$
,

where

(2.9)
$$D = \frac{3+n_1+n_2+n_3+n_4}{2}, \quad B = \frac{1-n_1-n_2}{2}.$$

Then, the order of the integration $\int dt$ and $\int ds$ can be changed, and the integration over dt yields the Mellin-Barnes integral [1], [2]:

408

$$(2.10) U_{4} = \frac{1}{\sqrt{\pi}} \frac{1}{2\pi i} \int_{s_{o}-i\infty}^{s_{o}+i\infty} \frac{\Gamma(-s+A)\Gamma(s+E)\Gamma(s+F)}{\Gamma(s+J)\Gamma(s+K)\Gamma(s+L)} ds$$

$$\times \int_{0}^{\infty} J_{3/2+n_{s}}(t) J_{3/2+n_{s}}(t) t^{-1+n_{1}+n_{s}+2s} dt$$

$$= \frac{1}{2\pi} \frac{1}{2\pi i} \int_{s_{o}-i\infty}^{s_{o}+i\infty} \frac{\Gamma(-s+A)\Gamma(-s+B)\Gamma(-s+C)\Gamma(s+D)\Gamma(s+E)\Gamma(s+F)}{\Gamma(-s+G)\Gamma(-s+H)\Gamma(-s+I)\Gamma(s+J)\Gamma(s+K)\Gamma(s+L)} ds$$

$$\equiv U_{5},$$

where

(2.12)

$$C = \frac{2 - n_1 - n_2}{2}, \qquad G = \frac{2 - n_1 - n_2 - n_3 + n_4}{2}, \qquad H = \frac{5 - n_1 - n_2 + n_3 + n_4}{2}, \qquad I = \frac{2 - n_1 - n_2 + n_3 - n_4}{2}.$$

The right-hand side of (2.11) belongs to the third type of Mellin-Barnes integrals [1], [2], in which the complex variable z is set equal to 1. Hence it is expressed as a Meijer *G*-function [2].

(2.13)
$$U_{5} = \frac{1}{2\pi} G_{66}^{33} \left(1 \begin{vmatrix} 1 - D, 1 - E, 1 - F; G, H, I \\ A, B, C; 1 - J, 1 - K, 1 - L \end{vmatrix} \right)$$

Because of the interrelationships of the quantities A, B, \dots, L , the above G-function cannot be expanded in the usual fashion as a sum of three generalized hypergeometric functions of the form ${}_{6}F_{5}$. However, limiting forms of the general expansion can be taken. In this connection, see [8, p. 14]. In the present instance, the resultant expressions depend on the interrelations between n_1, n_2, n_3 and n_4 . Thus, to avoid any specific configurations among the n_i , we evaluate the second integral representation in (2.10) by using the poles like $\Gamma(-s + A)$ which lie to the right of the path of integration.

III. Programing for Computers. We define G(s) by⁴

(3.1)
$$G(s) = \Gamma(s)$$
, when s is a positive integer,
or a positive or negative half odd integer

(3.2)
$$G(s) = \frac{(-)^{-s}}{(-s)!}, \text{ when } s \text{ is zero or a negative integer,} \\ (G(s) \text{ is residue of } \Gamma(s)).$$

Then (2.11) is given by

$$U_{5} = \frac{1}{2\pi} \sum_{\text{poles}} \frac{G(-s+A)G(-s+B)G(-s+C)G(s+D)G(s+E)G(s+F)}{G(-s+G)G(-s+H)G(-s+I)G(s+J)G(s+K)G(s+L)} \\ \equiv U_{6},$$

⁴ Meijer G-functions and G(s) defined here should not be confused.

where \sum_{poles} means a sum over poles of integrand of (2.11) on the right of the path of the integration.

The value of s which can be a pole is an integer or a half odd integer. When the value of an argument of a G-function in the numerator, say, -s + A, is a negative integer or zero for some integral or half odd integral value of s, a weight factor +1 is given to the corresponding G-function. When the value in the denominator, say, s + L, is a negative integer or zero, a factor -1 is given to the corresponding G-function. Determine weight factors for all G-functions in the numerator and in the denominator.

When the sum of weight factors of G-functions in the numerator and those in the denominator is equal to +1 for a value (integer or half odd integer) of s, then s is a simple pole. When it is equal to a positive integer n, s is a n-ple pole. When it is equal to zero or a negative integer, s is not a pole. In our example, double and higher-order poles do not appear.⁵

The values of G(-s + A), G(-s + B), \cdots , G(s + L), are picked out from a table of G(t) tabulated in a memory, and the values are substituted into (3.3); then it gives the residue of (2.11) at s. This process is repeated for every integral and half odd integral value of s from s_{\min} to s_{\max} , where s_{\min} and s_{\max} are the minimum and the maximum values of s which can be a pole, respectively.⁶ They are given by

(3.4)
$$s_{\min} = \operatorname{Min} (A, B), \qquad s_{\max} = \operatorname{Max} (G, H, I).$$

Since the maximum value of G(s) and the value of products of G(s) in the course of the calculation sometimes cause overflow or underflow, the table of log |G(s)| is tabulated in the memory in the actual calculation. With regard to the sign of G(s), sg(s) is defined for integral or half odd integral values of s as follows,

(3.5)
$$sg(s) = -1$$
, $(G(s) < 0)$, for $s < 0$ and $|2s| = 1$ or $2 \pmod{4}$,
 $sg(s) = +1$, $(G(s) > 0)$, otherwise.

Then, after each factor of log |G(s)| is added or subtracted, the sign is associated by

$$U_{6} = \frac{1}{2\pi} \sum_{\text{poles}} \text{sg} (-s + A) \text{sg} (-s + B) \text{sg} (-s + C) \text{sg} (s + D)$$

$$\times \text{sg} (s + E) \text{sg} (s + F) \text{sg} (-s + G) \text{sg} (-s + H) \text{sg} (-s + I)$$

$$\times \text{sg} (s + J) \text{sg} (s + K) \text{sg} (s + L)$$

$$(3.6) \qquad \times \exp \left[\log |G(-s + A)| + \log |G(-s + B)| + \log |G(-s + C)| + \log |G(s + D)| + \log |G(s + E)| + \log |G(s + F)| - \log |G(-s + G)| - \log |G(-s + H)| - \log |G(-s + I)| - \log |G(-s + I)| - \log |G(s + J)| - \log |G(s + K)| - \log |G(s + L)| \right].$$

410

⁵ When $n_1 + n_2 =$ even, all poles of $\Gamma(-s + C)$ are canceled by those of $\Gamma(-s + G) (n_3 \ge n_4)$ or of $\Gamma(-s + I) (n_3 \le n_4)$. When $n_1 + n_2 =$ odd, all poles of $\Gamma(-s + B)$ are canceled by those of $\Gamma(-s + G) (n_3 - n_4 > -1)$ or of $\Gamma(-s + I) (n_3 - n_4 \le -1)$. Poles of $\Gamma(-s + A)$ and $\Gamma(-s + B)$ do not coincide.

⁶ Poles of $\Gamma(-s+A)$ are canceled by those of $\Gamma(-s+I)$ for $I \leq s$ $(n_3 \geq n_4)$ or of $\Gamma(-s+G)$ for $G \leq s$ $(n_3 \leq n_4)$. When $n_1 + n_2 =$ even, poles of $\Gamma(-s+B)$ are canceled by those of $\Gamma(-s+H)$ for $H \leq s$. When $n_1 + n_2 =$ odd, poles of $\Gamma(-s+C)$ are canceled by those of $\Gamma(-s+H)$ for $H \leq s$. Hence, the number of poles is finite.

A program to calculate (1.1) was made using the method described in this section.

IV. $W_{3/2+n_1,3/2+n_2,3/2+n_3}^{5/2}(a, b, b)$. A similar argument can be carried out for the integrals of three-fold products of Bessel functions (1.2) by substituting the integral representation for the Bessel function

(4.1)
$$J_{3/2+n_1}(at) = \frac{1}{2\pi i} \int_{s_0-i\infty}^{s_0+i\infty} \frac{\Gamma(-s)}{\Gamma(5/2+n_1+s)} \left(\frac{at}{2}\right)^{3/2+n_1+2s} ds$$

into the first factor of (1.2), where

The integral (1.2) is shown to satisfy

(4.3)

$$U_{2} = \frac{1}{2} \cdot \frac{1}{\sqrt{\pi}} b^{3/2} \left(\frac{a}{2b}\right)^{3/2+n_{1}} \frac{1}{2\pi i} \int_{s_{o}-i\infty}^{s_{o}+i\infty} ds \left(\frac{a}{2b}\right)^{2s} \\
\times \frac{\Gamma(-s+A)\Gamma(-s+M)\Gamma(-s+N)\Gamma(s+P)}{\Gamma(-s+Q)\Gamma(-s+T)\Gamma(s+L)} \equiv U_{7}, \\
(4.4) \qquad -P < s_{0} < M,$$

where

$$A = 0, \qquad \qquad Q = \frac{2 - n_1 - n_2 + n_3}{2},$$
$$M = \frac{1 - n_1}{2}, \qquad \qquad R = \frac{5 - n_1 + n_2 + n_3}{2},$$
$$N = \frac{2 - n_1}{2}, \qquad \qquad T = \frac{2 - n_1 + n_2 - n_3}{2},$$
$$P = \frac{3 + n_1 + n_2 + n_3}{2}, \qquad \qquad L = \frac{5 + 2n_1}{2}.$$

(4.5)

The right-hand side of (4.3) belongs to the third type of Mellin-Barnes integrals
in which the complex variable z is put to be equal to
$$(a/2b)^2$$
. Hence, the value of
the integral can be obtained by calculating the sum of residues of the integrand at
the poles of $\Gamma(-s + A)$, $\Gamma(-s + M)$ and $\Gamma(-s + N)$ to the right of the path of
integration when $a \leq 2b$, and those at the poles of $\Gamma(s + P)$ to the left of the path of
integration when $a \geq 2b$. In particular $W_{3/2,3/2+n_2,3/2+n_3}^{5/2}$ (2, 1, 1) vanishes for $n_1 = 0$
and $n_2 + n_3$ (even) ≥ 2 , since no poles are found to the left of the path of integration.
Hereafter we consider the case where $a \leq 2b$.

The value s_0 must satisfy the condition of (4.2) and the convergence condition of the Weber-Schafheitlin's integral (4.4), simultaneously. Hence

(4.6)
$$U_{7} = \frac{1}{4(2\pi)^{1/2}} a^{3/2} \left(\frac{a}{2b}\right)^{n_{1}} \sum_{\text{poles}} \left(\frac{a}{2b}\right)^{2s} \times \frac{G(-s+A)G(-s+M)G(-s+N)G(s+P)}{G(-s+Q)G(-s+R)G(-s+T)G(s+L)} \equiv U_{8},$$
$$s_{\min} = \operatorname{Min}\left(A, M\right), \quad s_{\max} = \operatorname{Max}\left(Q, R, T\right).$$

The right-hand side of (4.6) is expressed as

(4.7)
$$U_8 = \frac{1}{2\sqrt{\pi}} b^{3/2} \left(\frac{a}{2b}\right)^{3/2+n_1} G_{44}^{31} \left(\left(\frac{a}{2b}\right)^2 \middle| \begin{array}{c} 1-P; Q, R, T\\ A, M, N; 1-L \end{array}\right).$$

Summation in (4.6) is to be carried out by the same method as the fourfold products of Bessel functions.

V. Tables. Tables of integrals

(5.1)
$$W^{4}_{3/2+n_{1},3/2+n_{2},3/2+n_{3},3/2+n_{4}}(1, 1, 1, 1)$$

for $n_1, n_2, n_3, n_4 \leq 10, n_1, + n_2 + n_3 + n_4 =$ even, of

(5.2)
$$W_{3/2+n_1,3/2+n_2,3/2+n_3}^{5/2}(a, b, b)$$

for $n_1, n_2, n_3 \leq 20, n_1 + n_2 + n_3 = even, a, b, c = 1$ and of (5.2) for $n_1 = 0, n_2, n_3$ $\leq 16, n_2 + n_3 = \text{even}, a, b, c = 1 \text{ or } 2 \text{ were calculated by the present method and a}$ copy was deposited as a document in the UMT file.⁷

Integrals $W_{\nu_1\nu_2\nu_3}^{\lambda}(a, b, b)$ and $W_{\nu_1\nu_2\nu_3\nu_4}^{\lambda}(a, a, b, b)$ for integral values of ν_i can be obtained by modifying the present method in such way that residues at double poles can be calculated. This can be done by storing $\Psi(n)$ and $\Psi(n + \frac{1}{2})$ ($\Psi(z) =$ $\Gamma'(z)/\Gamma(z)$ in the memory.

Integrals $W_{\nu_1\nu_2\nu_3}^{\lambda}(a, b, c)$ and $W_{\nu_1\nu_2\nu_3\nu_4}^{\lambda}(a, b, c, d)$ for different a, b, c, d are outside the range of applicability of the present method. They can be evaluated by the method of Appendix III in [3] for half integral values of ν_i . General results along these lines will be reported in the future.
