## **Modular Multiplication Without Trial Division**

## By Peter L. Montgomery

Abstract. Let N > 1. We present a method for multiplying two integers (called *N*-residues) modulo N while avoiding division by N. N-residues are represented in a nonstandard way, so this method is useful only if several computations are done modulo one N. The addition and subtraction algorithms are unchanged.

**1. Description.** Some algorithms [1], [2], [4], [5] require extensive modular arithmetic. We propose a representation of residue classes so as to speed modular multiplication without affecting the modular addition and subtraction algorithms.

Other recent algorithms for modular arithmetic appear in [3], [6].

Fix N > 1. Define an *N*-residue to be a residue class modulo *N*. Select a radix *R* coprime to *N* (possibly the machine word size or a power thereof) such that R > N and such that computations modulo *R* are inexpensive to process. Let  $R^{-1}$  and N' be integers satisfying  $0 < R^{-1} < N$  and 0 < N' < R and  $RR^{-1} - NN' = 1$ .

For  $0 \le i < N$ , let *i* represent the residue class containing  $iR^{-1} \mod N$ . This is a complete residue system. The rationale behind this selection is our ability to quickly compute  $TR^{-1} \mod N$  from T if  $0 \le T < RN$ , as shown in Algorithm REDC:

function REDC(T)  $m \leftarrow (T \mod R)N' \mod R [so 0 \le m < R]$   $t \leftarrow (T + mN)/R$ if  $t \ge N$  then return t - N else return t

To validate REDC, observe  $mN \equiv TN'N \equiv -T \mod R$ , so t is an integer. Also,  $tR \equiv T \mod N$  so  $t \equiv TR^{-1} \mod N$ . Thirdly,  $0 \leq T + mN < RN + RN$ , so  $0 \leq t < 2N$ .

If R and N are large, then T + mN may exceed the largest double-precision value. One can circumvent this by adjusting m so  $-R < m \le 0$ .

Given two numbers x and y between 0 and N - 1 inclusive, let z = REDC(xy). Then  $z \equiv (xy)R^{-1} \mod N$ , so  $(xR^{-1})(yR^{-1}) \equiv zR^{-1} \mod N$ . Also,  $0 \le z < N$ , so z is the product of x and y in this representation.

Other algorithms for operating on N-residues in this representation can be derived from the algorithms normally used. The addition algorithm is unchanged, since  $xR^{-1} + yR^{-1} \equiv zR^{-1} \mod N$  if and only if  $x + y \equiv z \mod N$ . Also unchanged are

the algorithms for subtraction, negation, equality/inequality test, multiplication by an integer, and greatest common divisor with N.

To convert an integer x to an N-residue, compute  $xR \mod N$ . Equivalently, compute REDC( $(x \mod N)(R^2 \mod N)$ ). Constants and inputs should be converted once, at the start of an algorithm. To convert an N-residue to an integer, pad it with leading zeros and apply Algorithm REDC (thereby multiplying it by  $R^{-1} \mod N$ ).

To invert an N-residue, observe  $(xR^{-1})^{-1} \equiv zR^{-1} \mod N$  if and only if  $z \equiv R^2x^{-1} \mod N$ . For modular division, observe  $(xR^{-1})(yR^{-1})^{-1} \equiv zR^{-1} \mod N$  if and only if  $z \equiv x(\text{REDC}(y))^{-1} \mod N$ .

The Jacobi symbol algorithm needs an extra negation if (R/N) = -1, since  $(xR^{-1}/N) = (x/N)(R/N)$ .

Let M|N. A change of modulus from N (using R = R(N)) to M (using R = R(M)) proceeds normally if R(M) = R(N). If  $R(M) \neq R(N)$ , multiply each N-residue by  $(R(N)/R(M))^{-1}$  mod M during the conversion.

**2.** Multiprecision Case. If N and R are multiprecision, then the computations of m and mN within REDC involve multiprecision arithmetic. Let b be the base used for multiprecision arithmetic, and assume  $R = b^n$ , where n > 0. Let  $T = (T_{2n-1}T_{2n-2} \cdots T_0)_b$  satisfy  $0 \le T < RN$ . We can compute  $TR^{-1} \mod N$  with n single-precision multiplications modulo R, n multiplications of single-precision integers by N, and some additions:

```
c \leftarrow 0
for i := 0 step 1 to n - 1 do
(dT_{i+n-1} \cdots T_i)_b \leftarrow (0T_{i+n-1} \cdots T_i)_b + N^*(T_iN' \mod R)
(cT_{i+n})_b \leftarrow c + d + T_{i+n}
[T is a multiple of b^{i+1}]
[T + cb^{i+n+1} is congruent mod N to the original T]
[0 \le T < (R + b^i)N]
end for
if (cT_{2n-1} \cdots T_n)_b \ge N then
return (cT_{2n-1} \cdots T_n)_b - N
else
return (T_{2n-1} \cdots T_n)_b
end if
```

Here variable c represents a delayed carry—it will always be 0 or 1.

3. Hardware Implementation. This algorithm is suitable for hardware or software. A hardware implementation can use a variation of these ideas to overlap the multiplication and reduction phases. Suppose  $R = 2^n$  and N is odd. Let  $x = (x_{n-1}x_{n-2} \cdots x_0)_2$ , where each  $x_i$  is 0 or 1. Let  $0 \le y < N$ . To compute  $xyR^{-1} \mod N$ , set  $S_0 = 0$  and  $S_{i+1}$  to  $(S_i + x_iy)/2$  or  $(S_i + x_iy + N)/2$ , whichever is an integer, for i = 0, 1, 2, ..., n - 1. By induction,  $2'S_i \equiv (x_{i-1} \cdots x_0)y \mod N$  and  $0 \le S_i < N + y < 2N$ . Therefore  $xyR^{-1} \mod N$  is either  $S_n$  or  $S_n - N$ . 1. J. M.
