

COMPUTATION OF THE ZEROS OF p -ADIC L -FUNCTIONS. II

R. ERNVALL AND T. METSÄNKYLÄ

ABSTRACT. The authors have carried out a computational study of the zeros of Kubota-Leopoldt p -adic L -functions. Results of this study have appeared recently in a previous article. The present paper is a sequel to that article, dealing with the computation of the zeros under certain conditions that complicate the original situation.

1. INTRODUCTION

This paper continues the authors' computational study, begun in [2], of the zeros of the Kubota-Leopoldt p -adic L -functions $L_p(s, \chi)$. We will discuss four themes, all of which came up but were left aside in [2].

In the following, the article [2] is referred to as Part I. When referring to an individual section or proposition of that paper we write, say, §I.3 or Proposition I.5. We retain the basic notation of Part I; in particular, p is an odd prime, $f_\theta(T) = \sum_{j=0}^{\infty} a_j T^j$ denotes the Iwasawa power series determined by the first factor θ of χ , and $\lambda = \lambda_\theta$ stands for the λ -invariant of this power series.

Our first question, considered in §2, concerns the computation of the zeros of $L_p(s, \chi)$ when the second factor of χ is nonprincipal. The remaining sections deal with the computation of the zeros T_1, \dots, T_λ of $f_\theta(T)$ under certain conditions that complicate the original situation discussed in Part I. Thus, in §3 there are two zeros T_1 and T_2 close to each other, §4 introduces types of the Newton polygon of $f_\theta(T)$ different from our two basic types, and the final §5 shows how to compute zeros T_k lying in wildly ramified extensions of \mathbb{Q}_p .

A sample of numerical results related to each of these sections is given in Tables VI–X at the end of the paper.

We recall that a crucial step in the computation of a zero T_0 of $f_\theta(T)$ is the determination of the extension $E = \mathbb{Q}_p(T_0)$ and of an initial approximation t_0 of T_0 satisfying the condition

$$f_\theta(t_0) \equiv 0 \pmod{\pi^{2\gamma+1}},$$

where π is a prime element of \mathcal{O}_E and $\gamma = v_\pi(f'_\theta(T_0))$. To accomplish this, one first reduces the possible candidates for E to a family of relatively few fields and expands T_0 π -adically with unknown coefficients; then E and t_0 will be

obtained by solving successively a sequence of *approximation congruences*

$$f_\theta(T_0) \equiv 0 \pmod{\pi^m}, \quad m = 1, 2, \dots, m_0,$$

denoted by $\mathcal{E}(\pi^m)$ below.

When describing the computation of T_0 , we usually assume, to fix ideas, that $a_0 = f_\theta(0)$ does not vanish. If $a_0 = 0$, the procedure is essentially the same; one just excludes the zero $T_0 = 0$, which is known to be simple, and then replaces $f_\theta(T)$ by $f_\theta(T)/T$. In this case we say that $f_\theta(T)$ is of *type Z*.

2. L-FUNCTIONS INVOLVING CHARACTERS OF THE SECOND KIND

In this section we are concerned with the zeros s_0 of $L_p(s, \theta\psi_n)$, where ψ_n is a nonprincipal character of the second kind. Recall that ψ_n is of order p^n and conductor p^{n+1} ($n \geq 1$). We will discuss the questions of how to find examples of $L_p(s, \theta\psi_n)$ having a zero s_0 , and how to compute this s_0 .

Suppose we have found a zero T_0 of some Iwasawa power series $f_\theta(T)$. By §I.3, if there is a corresponding zero s_0 of some $L_p(s, \theta\psi_n)$, then $s_0 = \log(1+T_0)/\log(1+dp)$ and $v_p(T_0) = 1/(p-1)p^{n-1}$. In the range of our computations, the only p -ordinals of T_0 of this form are $v_3(T_0) = 1/2$, $v_5(T_0) = 1/4$, and $v_3(T_0) = 1/6$, and the respective values of λ are 2, 4, and 6 (or 3, 5, and 7 when $f_\theta(T)$ is of type Z). Since, moreover, the coefficients of $f_\theta(T)$ in all examples are from \mathbb{Z}_p , Proposition I.5(i) shows that T_0 must belong to $\mathbb{Q}_p(\zeta_{p^n})$ in order that s_0 lie in D_s , the domain of definition of $L_p(s, \chi)$.

The case $v_3(T_0) = 1/6$, which leads to a wildly ramified extension $\mathbb{Q}_3(T_0)$, will be studied in §5. We found no example of this kind with $T_0 \in \mathbb{Q}_3(\zeta_9)$.

As for the other two cases, it follows from Proposition I.5(ii) that the condition $T_0 \in \mathbb{Q}_p(\zeta_p)$ is even sufficient for s_0 to be a zero of a $L_p(s, \theta\psi_1)$. We have the following practical criterion.

Proposition 1. *Let $\lambda = p - 1$ and $v_p(a_0) = 1$, so that $v_p(T_0) = 1/(p - 1)$. Then $T_0 \in \mathbb{Q}_p(\zeta_p)$ if and only if $a_{01} = a_{\lambda 0}$.*

Proof. The Newton polygon of $f_\theta(T)$ is of the “first type” discussed in §I.9. From that discussion it is seen that $T_0 \in \mathbb{Q}_p(\sqrt[p-r]{r})$, where r is determined by the conditions

$$\begin{aligned} T_0 &\equiv x\pi \pmod{\pi^2}, & 0 < x < p, \\ a_{01} + a_{\lambda 0}rx^{p-1} &\equiv 0 \pmod{p}. \end{aligned}$$

Since $\mathbb{Q}_p(\zeta_p) = \mathbb{Q}_p(\sqrt[p-r]{p})$, the assertion follows. \square

For $p = 5$ our numerical material contains five examples with $\lambda = 4$ and $v_5(a_0) = 1$, and one similar example of type Z. In all these, $T_0 \notin \mathbb{Q}_5(\zeta_5)$. Four of the examples are exhibited in Tables IV and V of Part I; the remaining two are $(5, 5708, 0)$ and $(5, -12712, 1)$.

Our main case is that of $p = 3$, $\lambda = 2$, and $v_3(a_0) = 1$. Applying the criterion of Proposition 1 to the tables computed in Program A (Part I), one finds numerous examples of this case which give zeros of $L_3(s, \theta\psi_1)$. Including some analogous cases with $\lambda = 3$, we settled 13 examples of this kind completely.

Before describing the computation, we observe that there are two characters $\psi_1 \pmod{9}$, say ψ_+ and ψ_- , identified by the equations $\psi_\pm(1 + 3d) = -\frac{1}{2} \pm \frac{\pi}{2}$, where $\pi = \sqrt{-3}$. A zero T_0 with $v_3(T_0) = 1/2$ may be written in the form $T_0 = 3b + c\pi$, where $b, c \in \mathbb{Z}_3$, $c \not\equiv 0 \pmod{3}$. Then, by Proposition I.3, the

number $s_0 = \log(1+T_0)/\log(1+3d)$ corresponding to $c \equiv +1 \pmod{3}$ is a zero of $L_3(s, \theta\psi_+)$, in fact, the only zero of this function (under the assumption that $\lambda = 2$). Its conjugate is of course the zero of $L_3(s, \theta\psi_-)$.

After computing $L_3(s, \theta)$, $f_\theta(T)$, T_0 , and s_0 in the usual way, we proceed with the computation of the function

$$L_3(s, \theta\psi_1) = \sum_{i=0}^{\infty} u'_i s^i.$$

As in §I.5, this means the approximation of u'_i by rational integers congruent to u'_i modulo a prescribed power p^M ; this makes sense since $u'_i \rightarrow 0$ as $i \rightarrow \infty$. Here we make use of Washington's formula with $\Phi = 9d$ in the way described in §§I.5, I.11. A lower bound for $v_p(u'_i)$ needed in the computation is provided by Proposition 2 below.

Recall that

$$(1) \quad L_p(s, \theta\psi) = f_\theta(\rho(1+dp)^s - 1),$$

where $\rho = \psi(1+dp)^{-1}$, $\psi = \psi_n$. To check the correctness of our $L_3(s, \theta\psi_1)$, we evaluated both sides of this formula for $s = 1$. As a final check it was verified that $L_3(s_0, \theta\psi_1)$ vanishes mod π^{M_1} , where (see the end of §I.11)

$$M_1 = \min \left(2M, \quad M - 3 + \min_{i>0} v_\pi(u'_i) \right).$$

By the remark at the end of the present section, $M_1 \geq M$.

Example. Let θ be the character defined by $(3, -1147, 1)$. The following table presents $L_3(s, \theta)$ (1st column) and $f_\theta(T)$ (3rd column) according to the same principles as the Tables I-V in Part I; see §I.10 for a description. The middle column lists the coefficients u'_0, \dots, u'_6 of $L_3(s, \theta\psi_\pm)$; here, $\pi = \sqrt{-3}$. The coefficients u'_i with $i > 6$ are zero to the accuracy displayed in this column.

0.11000	$0.0200 \pm 0.0122\pi$	0.11000
0.01122	$0.0111 \pm 0.1102\pi$	0.1102
0.01020	$0.0110 \pm 0.0002\pi$	1.100
0.00011	$0.0001 \pm 0.0220\pi$	0.20
0.00102	$0.0011 \pm 0.0000\pi$	2.0
0.00000	$0.0000 \pm 0.0001\pi$	0.
0.00011	$0.0001 \pm 0.0000\pi$	

The zeros of $f_\theta(T)$ are $T_{1,2} = 0.10 \pm 2.0\pi$ (approximately), and the corresponding numbers $s_{1,2} = 0.0 \pm (2.)\pi$ are the zeros of $L_3(s, \theta\psi_\mp)$. (The upper and lower signs correspond to each other.)

Table VI contains further examples of this kind. In Table VIa there are two similar examples with an additional pair of zeros of $f_\theta(T)$ and $L_3(s, \theta)$.

We conclude this section by proving the following estimate (cf. Proposition I.6).

Proposition 2. For any $\psi = \psi_n$ ($n \geq 1$), let $L_p(s, \theta\psi) = \sum_{i=0}^{\infty} u'_i s^i$. Then

$$v_p(u'_i) \geq i - \frac{i}{p-1} \quad (i = 0, 1, \dots).$$

Proof. Considering the right-hand side of (1), we write

$$\rho(1 + dp)^s - 1 = \rho \exp(s \log(1 + dp)) - 1 = \sum_{i=0}^{\infty} d_i s^i,$$

where $d_0 = \rho - 1$ and $d_i = \rho (\log(1 + dp))^i / i!$ for $i \geq 1$. This gives the expansions

$$(\rho(1 + dp)^s - 1)^j = \sum_{i=0}^{\infty} d_{ij} s^i \quad (j = 0, 1, \dots)$$

with $d_{00} = 1$, $d_{i0} = 0$ ($i \geq 1$), and

$$d_{ij} = \sum_{t_1 + \dots + t_j = i} d_{t_1} \cdots d_{t_j} \quad (i \geq 0, j \geq 1).$$

We show that

$$(2) \quad v_p(d_{ij}) \geq jv_p(\rho - 1) + \left(1 - \frac{1}{p-1}\right) i \quad (i \geq 0, j \geq 0).$$

This is trivial for $j = 0$; so let $j \geq 1$. Denote by j' the number of positive indices in a set $\{t_1, \dots, t_j\}$ with $t_1 + \dots + t_j = i$. For simplicity of notation, assume that the positive indices are just $t_1, \dots, t_{j'}$, so that

$$\sum_{\nu=1}^j v_p(d_{t_\nu}) = (j - j')v_p(\rho - 1) + \sum_{\nu=1}^{j'} v_p(d_{t_\nu}).$$

Since $v_p(\rho - 1) \leq 1/(p - 1)$ and $v_p(d_{t_\nu}) = t_\nu - v_p(t_\nu!) \geq t_\nu - (t_\nu - 1)/(p - 1)$ ($\nu = 1, \dots, j'$), we obtain the estimate

$$\sum_{\nu=1}^j v_p(d_{t_\nu}) \geq jv_p(\rho - 1) + \left(1 - \frac{1}{p-1}\right) \sum_{\nu=1}^{j'} t_\nu.$$

This proves (2).

Equation (1) now allows us to write

$$\sum_{i=0}^{\infty} u'_i s^i = \lim_{J \rightarrow \infty} \sum_{j=0}^J a_j \sum_{i=0}^{\infty} d_{ij} s^i = \lim_{J \rightarrow \infty} \sum_{i=0}^{\infty} \left(\sum_{j=0}^J a_j d_{ij} \right) s^i,$$

whenever $s \in D_s$. Restrict s for a moment to the subset of D_s defined by $v_p(s) > 0$. Then it follows, in view of (2), that

$$\sum_{i=0}^{\infty} u'_i s^i = \sum_{i=0}^{\infty} \left(\sum_{j=0}^{\infty} a_j d_{ij} \right) s^i$$

(see Lemma in [3, p. 53]). Hence,

$$(3) \quad u'_i = \sum_{j=0}^{\infty} a_j d_{ij} \quad (i = 0, 1, \dots),$$

and this together with (2) implies the proposition. \square

Remark. Let, in particular, $\lambda = p - 1$ and $v_p(a_0) = 1$. Then the coefficients of the series for $L_p(s, \theta\psi_1)$ satisfy the stronger inequality

$$v_p(u'_i) \geq i - \frac{i}{p-1} + 1 \quad (i = 0, 1, \dots).$$

This is seen from (3) and (2) upon observing that $v_p(a_j) \geq 1$ for $j = 0, \dots, p - 2$ and $jv_p(p - 1) \geq 1$ for $j \geq p - 1$. In the range of our computations, $v_p(u'_i)$ attains this lower bound for most values of i .

3. TWO ZEROS CLOSE TO EACH OTHER

This section continues our study of the case $\lambda = 2$, $v_p(a_0) = 2$ in which the Newton polygon of $f_\theta(T)$ is of the “second type” considered in §I.9. This case was settled under the assumption that the two zeros T_1 and T_2 (denoted by T'_0 and T''_0 in §I.9) satisfy $v_p(T_1 - T_2) < 2$. We now describe how to deal with examples in which $v_p(T_1 - T_2)$ is bigger. As before, it is assumed throughout that $T_1 \neq T_2$.

We begin with the following proposition that will also be needed in §4.

Proposition 3. *If all the zeros T_1, \dots, T_λ of $f_\theta(T)$ are pairwise distinct, then*

$$v_p(f'_\theta(T_k)) = \sum_{\substack{j=1 \\ j \neq k}}^{\lambda} v_p(T_k - T_j) \quad (k = 1, \dots, \lambda).$$

Proof. By the p -adic Weierstrass preparation theorem (see §I.2),

$$f_\theta(T) = u_\theta(T)w_\theta(T),$$

where $u_\theta(T)$ is an invertible power series and $w_\theta(T)$ a monic polynomial of degree λ having T_1, \dots, T_λ as its zeros. Differentiate this equation to obtain $f'_\theta(T_k) = u_\theta(T_k)w'_\theta(T_k)$ and, hence, $v_p(f'_\theta(T_k)) = v_p(w'_\theta(T_k))$. \square

Going back to the above case, suppose that the rational integers x, y , and r fulfil the conditions

$$0 < x < p, \quad 0 \leq y < p, \quad r = 1 \text{ or } g \text{ (a primitive root of } p),$$

$$T_{1,2} \equiv xp \pm yp\sqrt{rp} \pmod{p^2}.$$

Such numbers are found in the way presented in §I.9. In particular, if $y = 0$, then $v_p(T_1 - T_2) \geq 2$, and we may put

$$T_k \equiv xp + z_k p^2 \pmod{p^{5/2}} \quad (k = 1, 2),$$

where z_1 and z_2 are either in \mathbb{Z} or in $\mathbb{Z}[\sqrt{g}]$. Looking at the coefficient of p^4 in the approximation congruence mod p^5 , we infer a condition

$$d_0 + d_1 z_k + a_{20} z_k^2 \equiv 0 \pmod{p},$$

where d_0 and d_1 are rational integers determined by x and by the first digits of a_0, \dots, a_4 .

If the solutions z_1 and z_2 of the last congruence are distinct, then $v_p(T_1 - T_2) = 2$ and Krasner’s lemma implies that $T_k - xp \in \mathbb{Q}_p(z_k)$. Thus, E/\mathbb{Q}_p is unramified, and we have $\gamma = v_p(f'_\theta(T_k)) = 2$ by Proposition 3. In this case the algorithm may be started with $t_k = xp + z_k p^2$.

We found two examples of this kind, for the characters $(3, 13564, 0)$ and $(3, -11188, 1)$, both with $E = \mathbb{Q}_3(\sqrt{2})$. They are presented in detail in Table VII.

Secondly, suppose that $z_1 = z_2 = z$. Then $z \in \mathbb{Z}$, and one proceeds with the congruence

$$T_{1,2} \equiv xp + zp^2 \pm up^2\sqrt{rp} \pmod{p^3},$$

where $u \in \mathbb{Z}$, $0 \leq u < p$. Put $\pi = \sqrt{rp}$. To find u and r , one has to solve a congruence of the form $ru^2 \equiv l \pmod{p}$, where $l \in \mathbb{Z}$; this is in fact obtained from $\mathcal{E}(\pi^{11})$. If $u \neq 0$, we see that $E = \mathbb{Q}_p(\pi)$ and $v_p(T_1 - T_2) = 5/2$, and Proposition 3 gives $\gamma = v_\pi(f'_\theta(T_k)) = 5$. Hence, we may take $t_{1,2} = xp + zp^2 \pm up^2\pi$.

In Table VII, the example for the character $(3, 13784, 0)$ belongs to this category. Table VIIa shows two similar examples of type Z .

If $u = 0$, i.e., $v_p(T_1 - T_2) \geq 3$, we are in the analogous situation we started from. There is no example of this in our material.

4. VARIOUS TYPES OF THE NEWTON POLYGON

We now show how to deal with some classes of the Newton polygon of $f_\theta(T)$ which differ from our two basic types. They are called Types 3–6 below; each of them was met in the computations and will be treated in a generality sufficient to settle our particular examples.

The examples mentioned in this section appear in Table VIII unless otherwise stated.

Type 3. $v_p(a_0) > 2$, $v_p(a_1) = 1$, $\lambda = 2$.

The two zeros T_1 and T_2 satisfy $v_p(T_1) = v_p(a_0) - 1 > 1$ and $v_p(T_2) = 1$. Hence they lie in \mathbb{Q}_p . This is a slight variant of our “second type”, and from §I.9 it is seen, on putting $a_{02} = 0$, that one may start with $t_k = x_k p$ ($k = 1, 2$), where $x_1 = 0$ and x_2 is the root of the congruence $a_{11} + a_{20}x \equiv 0 \pmod{p}$.

Examples of this kind are obtained for the characters $(5, 3101, 0)$, $(5, -4371, 1)$, $(11, -723, 1)$, the last two being of type Z . The example $(3, -1399, 1)$ in Table II (Part I) also belongs to this family.

Type 4. $v_p(a_0) = c > 1$, $v_p(a_k) > c(1 - k/\lambda)$ for $k = 1, \dots, \lambda - 1$, $\lambda (> 1)$ prime to c and p .

The Newton polygon has one nonzero slope, and this equals $-c/\lambda$. As in the case of the “first type”, the zeros $T_0 (= T_1, \dots, T_\lambda)$ are in fully ramified extensions $E = \mathbb{Q}_p(\sqrt[\lambda]{rp})$. Because c and p are prime to λ , one easily verifies that $\gamma = v_\pi(\lambda a_\lambda T_0^{\lambda-1}) = (\lambda - 1)c$. If $\lambda = 2$, one has to solve for x and r the congruence $a_{0c} + a_{20}r^c x^2 \equiv 0 \pmod{p}$, obtained from $\mathcal{E}(\pi^{2c+1})$, and then take $t_0 = x\pi^c$. For $\lambda > 2$ the procedure is similar but more complicated.

We have two examples with $c = 3$ and $\lambda = 2$, namely for $(3, 1901, 0)$ and $(5, 12056, 2)$, and one similar example of type Z , for $(5, -7816, 1)$. Table III in Part I gives an example with $(5, 1317, 0)$ in which $c = 2$ and $\lambda = 3$.

Type 5. $v_p(a_0) = 2$, $v_p(a_1) \geq 2$, $\lambda = 4$.

As in Type 4, there is but one nonzero slope, this time equal to $-1/2$. The zeros T_1, \dots, T_4 lie in fully ramified quartic extensions $E = \mathbb{Q}_p(\sqrt[4]{rp})$ or, if this is not the case, either in quadratic or biquadratic extensions of \mathbb{Q}_p (here “biquadratic” means “a composite of two quadratic”).

An example of the former kind is given by $(3, 1541, 0)$. The computation

is analogous to that in Type 4; note that Proposition 3 yields $\gamma = 7$ (see Table VIII). On the other hand, for the character $(3, 4204, 0)$ one rules out the fields $\mathbb{Q}_3(\sqrt[3]{\pm 3})$ by using $\mathcal{E}(\pi^9)$, and it turns out that the zeros are contained in $\mathbb{Q}_3(\sqrt{3}, \sqrt{2})$. In this case there is no zero of any $L_3(s, \theta\psi_n)$, $n \geq 0$, corresponding to T_0 ; indeed, $v_3(\log(1 + T_0)) = 1/2$, and so $v_3(s_0) = -1/2$.

In these two examples, the approximate values of the zeros given in Table VIII are easily computed by hand. A third example of the same kind, not included in the tables, is $(3, 7244, 0)$. In this case we have $E = \mathbb{Q}_3(\sqrt[3]{-3})$.

Type 6. $v_p(a_0) \geq 2$, $v_p(a_1) = 1$, $\lambda \geq 3$, $\lambda - 1$ prime to p .

Among the zeros $T_0 = T_k$, $k = 1, \dots, \lambda$, there is one, say T_1 , belonging to \mathbb{Q}_p and satisfying $v_p(T_1) \geq v_p(a_0) - 1 \geq 1$. The other zeros satisfy $v_p(T_k) = 1/(\lambda - 1)$ ($k = 2, \dots, \lambda$). For $T_0 = T_1$, Proposition 3 yields

$$\gamma = \sum_{j=2}^{\lambda} v_p(T_1 - T_j) = \sum_{j=2}^{\lambda} \frac{1}{\lambda - 1} = 1.$$

Thus, it is sufficient to look at $\mathcal{E}(p^3)$, and this gives $t_0 = xp$ with $x \equiv -a_{02}/a_{11} \pmod{p}$.

The computation of the remaining zeros is analogous to that in the “first type”. In particular, E/\mathbb{Q}_p is a fully and tamely ramified extension of degree $\lambda - 1$. We find that $v_p(T_k - T_j) = 1/(\lambda - 1)$ for $j = 1, \dots, \lambda$, $j \neq k$, and so $\gamma = \lambda - 1$.

To the first zero T_1 there always corresponds a zero s_1 of $L_p(s, \theta)$. The same holds true for T_2, \dots, T_λ in the case $\lambda < p$, while the situation varies for $\lambda \geq p$.

Our examples with $\lambda = 3 < p$ are the characters $(5, 4924, 2)$ and $(7, -4072, 5)$. The character $(3, -25528, 1)$ has $\lambda = 5$ (computed first by Kobayashi), and s_2, \dots, s_5 lie outside of D_s . So also do s_2, s_3 in the example $(3, 3512, 0)$, where $\lambda = 3$. Compare this example with $(3, 7804, 0)$ from Table VIa: here, too, $\lambda = 3$ but s_2 and s_3 are zeros of $L_3(s, \theta\psi_\pm)$. Finally, the character $(3, -5051, 1)$ in Table V (Part I), for which $f_\theta(T)$ is of type Z , also fits this category.

5. WILDLY RAMIFIED EXTENSIONS

All examples of wildly ramified extensions E/\mathbb{Q}_p were found for $p = 3$. The degree of the extensions is 3 or 6.

Consider first the case of cubic extensions. Let $\lambda = 3$ and $v_3(a_0) = 1$, so that $v_3(T_0) = 1/3$ and E/\mathbb{Q}_3 is indeed wildly ramified of degree 3. One may identify E (up to conjugates) by providing a cubic Eisenstein polynomial $r(X) \in \mathbb{Z}_3[X]$ such that $E = \mathbb{Q}_3(\pi)$ with $r(\pi) = 0$. In the table below, the list of 11 such polynomials $r(X)$ corresponds to a complete system of nonconjugate fields E . This list is extracted from results by Amano [1], who characterizes in this way all ramified extensions of degree p over any finite extension of \mathbb{Q}_p .

We will give a further characterization of the fields E , better suited for their computational identification. Note that every $r(X)$ is of the form

$$r(X) = X^3 - 3aX^2 - 3bX - 3c,$$

where $a, b, c \in \mathbb{Z}$ with $c \equiv 1 \pmod{3}$. Let π and E be as above. We have $3 = \epsilon\pi^3$, with ϵ a unit of \mathcal{O}_E , and from $r(\pi) = 0$ it follows that

$\epsilon = 1/(c + b\pi + a\pi^2)$. In particular, $\epsilon \equiv 1 \pmod{\pi}$. Write

$$\epsilon = 1 + \sum_{\nu=1}^{\infty} \epsilon_{\nu} \pi^{\nu}, \quad \epsilon_{\nu} \in \{0, \pm 1\}.$$

A straightforward calculation shows that our fields E can be identified by the triple $(\epsilon_1, \epsilon_2, \epsilon_3)$ as indicated in the table.

E	$r(X)$	$(\epsilon_1, \epsilon_2, \epsilon_3)$	E	$r(X)$	$(\epsilon_1, \epsilon_2, \epsilon_3)$
A_1	$X^3 - 3X - 3$	$(-1, +1, -1)$	C_1	$X^3 + 3X^2 - 12$	$(0, +1, -1)$
A_2	$X^3 + 3X - 3$	$(+1, +1, +1)$	C_2	$X^3 + 3X^2 - 3$	$(0, +1, 0)$
B_1	$X^3 - 3X^2 - 12$	$(0, -1, -1)$	C_3	$X^3 + 3X^2 + 6$	$(0, +1, +1)$
B_2	$X^3 - 3X^2 - 3$	$(0, -1, 0)$	P_1	$X^3 - 12$	$(0, 0, -1)$
B_3	$X^3 - 3X^2 + 6$	$(0, -1, +1)$	P_2	$X^3 - 3$	$(0, 0, 0)$
			P_3	$X^3 + 6$	$(0, 0, +1)$

Here the fields are labeled with A_1, A_2, B_1 , etc. The extension E/\mathbb{Q}_3 is cyclic for $E = C_1, C_2, C_3$ and pure for $E = P_1, P_2, P_3$.

We computed 17 examples in which the zeros belong to the fields of this table; eight of them were selected to be exhibited in Table IX. In the entire sample of 17 fields, A_1 and A_2 occur five times each, supporting the natural hypothesis that the values of ϵ_1 be randomly distributed.

The functions $L_3(s, \theta)$ and $f_{\theta}(T)$ were computed with the parameter $\eta = 16$. This implies, by Propositions I.12 and I.7, that the coefficients a_j are obtained mod 3^{8-j} ($j = 0, \dots, 7$). It is seen below that this accuracy allows us to determine the field E in all examples but one, and to find the zeros

$$T_0 = \sum_{\nu=1}^{\infty} x_{\nu} \pi^{\nu} \quad (x_{\nu} \in \{0, \pm 1\}, x_1 \neq 0)$$

to 1–4 x_{ν} -places. We computed T_0 by hand, thus avoiding the rather tedious implementation of the arithmetic of the fields in question. The results were checked by computing $f_{\theta}(T_0)$. From §I.3 it follows that the corresponding numbers s_0 are not zeros of any $L_3(s, \theta\psi_n)$; hence they are ignored.

To find E and T_0 , start with the approximation congruence $\mathcal{E}(\pi^5)$. This reduces to the congruences

$$a_{01} + a_{30}x_1 \equiv 0, \quad a_{01}\epsilon_1 + a_{11}x_1 + a_{40} \equiv 0 \pmod{3},$$

which give us x_1 and ϵ_1 . If $\epsilon_1 = -1$ or $+1$, the field is A_1 or A_2 , respectively, and the coefficients $\epsilon_2, \epsilon_3, \dots$ are determined by the equation $\epsilon = 1/(1 \pm \pi)$. Better approximations for T_0 then follow easily from $\mathcal{E}(\pi^m)$ for bigger exponents m .

In Table IX, the characters $(3; -3592, 1)$ and $(3, 1781, 0)$ are examples giving the field A_1 . The latter requires slightly different techniques since $v_3(a_0) = 2$. In both examples, the zeros T_1, T_2, T_3 lie in conjugate extensions generated by the roots $\pi = \pi_k$ of $r(X) = 0$ ($k = 1, 2, 3$).

Similarly, the characters $(3, 281, 0)$, $(3, -311, 1)$, and $(3, -2132, 1)$ yield examples in which $E = A_2$. The first of these is also mentioned in §I.10, with another normalization of $r(X)$. The second example is of type Z , while the third shows a function $f_{\theta}(T)$ with two zeros (one trivial) in \mathbb{Q}_3 .

Here are the other examples of A_1 and A_2 computed by us.

Example 1. For π_k a zero of $X^3 - 3X - 3$ ($k = 1, 2, 3$),

$$\begin{aligned} (3, 1397, 0) : T_k &\equiv \pi_k - \pi_k^2 - \pi_k^4 \pmod{\pi_k^5}, \\ (3, 5368, 0) : T_k &\equiv -\pi_k - \pi_k^2 - \pi_k^3 + \pi_k^4 \pmod{\pi_k^5}, \\ (3, 6712, 0) : T_k &\equiv -\pi_k^2 + \pi_k^4 \pmod{\pi_k^5}. \end{aligned}$$

Example 2. $(3, -2920, 1) : \pi_k$ zero of $X^3 + 3X - 3$ ($k = 1, 2, 3$),

$$T_k \equiv \pi_k + \pi_k^2 + \pi_k^4 \pmod{\pi_k^5}.$$

Example 3. $(3, -4184, 1) : T_1 = 0, s_1 = 0,$

$$\begin{aligned} \pi_k \text{ zero of } X^3 + 3X - 3 \quad (k = 2, 3, 4), \\ T_k \equiv \pi_k - \pi_k^2 + \pi_k^3 \pmod{\pi_k^4}. \end{aligned}$$

If $\epsilon_1 = 0$, we compute ϵ_2 from the congruence

$$-a_{01}\epsilon_2 \equiv a_{50}x_1 + a_{21} \pmod{3},$$

which is a consequence of $\mathcal{E}(\pi^6)$.

Let first $\epsilon_2 = 1$, so that E/\mathbb{Q}_3 is cyclic. Then $\mathcal{E}(\pi^7)$ gives ϵ_3 and so fixes E . When computing further places for T_0 , one should observe that E now contains all the three zeros of $f_\theta(T)$.

We have two examples of cyclic fields, in fact, of $E = C_1$. One, included in Table IX, is for $(3, 2504, 0)$, the other is given below.

Example 4. $(3, 5624, 0) : \pi$ zero of $X^3 + 3X^2 - 12$,

$$T_1 \equiv -\pi - \pi^3, \quad T_2 \equiv -\pi + \pi^2 - \pi^3, \quad T_3 \equiv -\pi - \pi^2 \pmod{\pi^4}.$$

Secondly, suppose that $\epsilon_2 = 0$. Then E is a pure extension of \mathbb{Q}_3 and one finds ϵ_3 and x_2 by solving simultaneously a pair of congruences produced by $\mathcal{E}(\pi^8)$.

In Table IX, this case is represented by the characters $(3, 4172, 0)$ and $(3, -1144, 1)$, which lead to the fields $\mathbb{Q}_3(\sqrt[3]{12})$ and $\mathbb{Q}_3(\sqrt[3]{-6})$, respectively. The next two examples give our other characters of this kind. Example 6 introduces a case with $\lambda = 4$; here the ultimate identification of E must be left open.

Example 5. For π_k a zero of $X^3 + 6$ ($k = 1, 2, 3$),

$$\begin{aligned} (3, 401, 0) : T_k &\equiv -\pi_k + \pi_k^2 \pmod{\pi_k^3}, \\ (3, 4472, 0) : T_k &\equiv \pi_k + \pi_k^2 \pmod{\pi_k^3}. \end{aligned}$$

Example 6. $(3, 6856, 0) : T_1 = 0.2201, s_1 = 2.000,$

$$\begin{aligned} \pi_k \text{ zero of } X^3 - a \quad (k = 2, 3, 4) \text{ with } a = 4, 1, \\ \text{or } -2, \\ T_k \equiv \pi_k \pmod{\pi_k^2}. \end{aligned}$$

After this, it is also clear how to deal with $\epsilon_2 = -1$ corresponding to the fields B_1, B_2, B_3 . We have no example of these fields.

Now let us turn to the case of sextic extensions. The basic case is the one with $\lambda = 6$ and $v_3(a_0) = 1$. As usual, put $E = \mathbb{Q}_3(T_0) = \mathbb{Q}_3(\pi)$.

Proposition 4. For a fully ramified sextic extension $E = \mathbb{Q}_3(\pi)$, let ϵ be the unit of the ring \mathcal{O}_E defined by the equation $3 = \epsilon\pi^6$. The field E contains the subfield $\mathbb{Q}_3(\sqrt{3})$ or $\mathbb{Q}_3(\sqrt{-3})$ according as $\epsilon \equiv 1$ or $\epsilon \equiv -1 \pmod{\pi}$, respectively.

Proof. The polynomial $q(X) = X^2 \mp 3$ satisfies $v_\pi(q'(\pi^3)) = 3$ and $q(\pi^3) = \pi^6(1 \mp \epsilon) \equiv 0 \pmod{\pi^7}$ provided that $\epsilon \equiv \pm 1 \pmod{\pi}$. \square

It follows that E is a ramified cubic extension of $\mathbb{Q}_3(\sqrt{3})$ or $\mathbb{Q}_3(\sqrt{-3})$. Hence, it can be classified in the way shown by Amano in [1]. We do not write down the complete classification but, rather, show how to handle the specific examples we have of this case. They are the three examples presented in Table X, two of them with $\lambda = 6$ and one with $\lambda = 7$ and $f_\theta(T)$ of type Z . In these examples we chose the truncation parameter $\eta = 18$ or 20 according as $\lambda = 6$ or 7 , respectively. This enables us to identify E and compute $T_0 \pmod{\pi^3}$. As mentioned in §2, we never have $E = \mathbb{Q}_3(\zeta_9)$; hence, we do not compute s_0 .

Put $\rho = \sqrt{(-1)^z 3}$, where $z = 0$ or 1 . By Proposition 4, $E = \mathbb{Q}_3(\rho, \pi)$, where π is a zero of an Eisenstein polynomial $r(X) \in \mathbb{Q}_3(\rho)[X]$. From [1] we find that it suffices to consider the polynomials

$$r(X) = X^3 - a\rho X^2 - b\rho X - c\rho,$$

where $a, b, c \in \mathbb{Z}$ and $c \equiv 1 \pmod{\rho}$. Let κ be the unit in $\mathbb{Q}_3(\rho)$ such that $\rho = \kappa\pi^3$. A similar argument as before yields $\kappa = 1/(c + b\pi + a\pi^2)$, and we may write

$$\kappa = 1 + \sum_{\nu=1}^{\infty} \kappa_\nu \pi^\nu, \quad \kappa_\nu \in \{0, \pm 1\}.$$

With the usual notation $T_0 = \sum_{\nu=1}^{\infty} x_\nu \pi^\nu$ (where $x_1 \neq 0$) we get from $\mathcal{E}(\pi^8)$ the congruences

$$(4) \quad (-1)^z a_{01} + a_{60} \equiv 0, \quad -2a_{01}\kappa_1 \equiv (a_{11} + (-1)^z a_{70})x_1 \pmod{3}.$$

The former determines ρ , and the latter tells us, first, whether or not $\kappa_1 = 0$. If $\kappa_1 \neq 0$ —as is the case in our examples—then $b \neq 0$, and we arrive, by [1], at the polynomials

$$r(X) = X^3 \mp \rho X - \rho,$$

which generate six ramified extensions of $\mathbb{Q}_3(\rho)$. The six zeros of $f_\theta(T)$ are contained in these fields, one in each. It also follows that $\kappa = 1/(1 \pm \pi)$ and so, in particular, $\kappa_2 = 1$. Hence the approximation congruence $\mathcal{E}(\pi^9)$ enables us to compute x_2 .

In case one is interested just in knowing whether or not $E = \mathbb{Q}_3(\zeta_9)$, it is worth noting that (4) yields the following necessary conditions for this equality: $a_{01} = a_{60}$, $a_{11} = a_{70}$. Indeed, we have $z = 1$ and $\kappa_1 = 0$ in this case.

In our examples obtained for the characters $(3, -7108, 1)$ and $(3, -20692, 1)$, the first congruence in (4) gives the result $z = 0$ and $z = 1$, respectively, and the second gives $\kappa_1 = x_1$. For the third character $(3, -1832, 1)$ we find that $z = 0$ and $\kappa_1 = -x_1$. See Table X for the full result.
