8 [9].– J. P. Kulik, *Magnus Canon Divisorum* $\cdots$, 8 ms. volumes (v. 2 now missing), deposited in the Library of the Academy of Sciences, Vienna in 1867.

A photostatic copy of that portion of v. 1 consisting of pages 260 through 416 has been deposited by D. H. Lehmer in the UMT file. This portion of Kulik's monumental table gives the least prime factor for all integers not divisible by 2, 3, or 5 between 9,000,000 and 12,642,600. The deposited copy includes handwritten corrections by Professor Lehmer inserted in the margins.

A detailed description of the complete table has been published by Joffe [1], superseding that of D. N. Lehmer [2].

In 1948 an announcement [3] was made that the Carnegie Institution of Washington had made in the preceding year a negative microfilm of this same portion of v. 1 and that it was prepared to supply positive microfilm copies at a nominal charge ($1.00 per copy at that time).

9 [9].– Sigekatu Kuroda, *Table of Class Numbers, h(p) Greater than* 1, *for Fields* $Q(\sqrt{p})$, $p \equiv 1$ (mod 4) $\leqslant$ 2776817, University of Maryland, 1965, copy deposited in the UMT file.

The table consists of 88 Xeroxed computer sheets containing class numbers $h(p)$ for primes of the form $p = 4n + 1$. The purpose of the computation was not simply to calculate $h(p)$, but to test a conjectured method of doing so. It is well known that every ideal class of $Q(\sqrt{p})$ contains an integral ideal with norm $< B = \frac{1}{2}\sqrt{p}$. Also the class number h is odd, the nonprincipal classes (if $h > 1$) occurring in conjugate pairs $C_i, C_i' = C_i^{-1}$, $1 \leqslant i \leqslant h' = \frac{1}{2}(h - 1)$. The conjecture states that the h' classes C_i can be represented by integral ideals *all having distinct norms less than* B.

Thus, only those p with $h(p) > 1$ were printed. There are $22 \cdot 2^{10} = 22528$ such primes up to $p = 2776817$. A printed count shows that altogether 100811 cases were computed; thus 78283 cases with $h = 1$ are omitted. The table lists the primes p and the class numbers $h(p)$ on alternate pages. Every other page contains 512 primes in 16 columns and 32 rows, each position identified by a number in base 32. The class number $h(p)$ is found on the next sheet and in the same position as p, cf. [1]. The class numbers are written in base 32 and followed by a symbol $(P, Q, C,$ or $D)$ indicating that the conjecture was verified for that case. The primes p were printed both in decimal and in base 32. The copy deposited contains the decimal version except for the first two pages. These were missing from the reviewer's copy of the table
