

A Galerkin Method for a Nonlinear Dirichlet Problem

By Jim Douglas, Jr. and Todd Dupont

Abstract. A Galerkin method due to Nitsche for treating the Dirichlet problem for a linear second-order elliptic equation is extended to cover the nonlinear equation $\nabla \cdot (a(x, u)\nabla u) = f$. The asymptotic error estimates are of the same form as in the linear case. Newton's method can be used to solve the nonlinear algebraic equations.

1. Introduction. We shall present asymptotic error estimates for a Galerkin method for the approximate solution of the nonlinear Dirichlet problem

$$(1) \quad \begin{aligned} -\nabla \cdot (a(x, u)\nabla u) &= f(x) \quad \text{on } \Omega, \\ u(x) &= g(x) \quad \text{on } \partial\Omega, \end{aligned}$$

where Ω is a bounded domain in \mathbf{R}^n with $n \leq 3$. Assume that Ω is locally on one side of its smooth boundary $\partial\Omega$, that $a(x, u)$ is a twice continuously differentiable mapping of $\bar{\Omega} \times \mathbf{R}$ into $[\alpha_0, \alpha_1]$, where $0 < \alpha_0 \leq \alpha_1 < \infty$, and that the derivatives of $a(x, r)$ through second order are bounded on $\bar{\Omega} \times \mathbf{R}$. As we shall see later, it follows from well-known regularity results and a uniqueness theorem of Douglas-Dupont-Serrin [1] that if, for some $\alpha \in (0, 1)$, $f \in C^\alpha(\bar{\Omega})$ and if g can be extended to $\bar{\Omega}$ to be in $C^{2+\alpha}(\bar{\Omega})$, then there exists a unique weak solution u of (1) and, moreover, $u \in C^{2+\alpha}(\bar{\Omega})$. (The class $C^{k+\alpha}(\bar{\Omega})$ consists of all functions whose derivatives through order k are Hölder continuous of order α on $\bar{\Omega}$.)

The Galerkin method we shall employ is the straightforward generalization of a method of Nitsche [3] to this nonlinear case and the form of the asymptotic error estimate produced for this method is essentially the same as in the corresponding linear case. The primary tool used in proving these error estimates is the fact that the formal derivative,

$$(2) \quad Lw = -\nabla \cdot (a(x, u)\nabla w + wa_u(x, u)\nabla u),$$

of the elliptic operator in (1) is a linear elliptic operator for which the Dirichlet problem has a unique solution; this (nonobvious) fact follows from [1]. The nonsingularity of the Dirichlet problem for (2) is also used in showing that the nonlinear algebraic equations arising in the Galerkin method can be solved by Newton's method provided a sufficiently good approximation of the answer can be found with which to begin the Newton iteration.

2. The Approximate Solution. For $1 \leq p \leq \infty$ and k a nonnegative integer, let $W_p^k(\Omega)$ be the functions in $L^p(\Omega)$ whose distribution derivatives through order k are also in $L^p(\Omega)$. Take $\|\cdot\|_{W_p^k(\Omega)}$ to be the natural norm on $W_p^k(\Omega)$:

$$\|V\|_{W_p^k(\Omega)} = \left[\sum_{|\alpha| \leq k} \|D^\alpha V\|_{L^p(\Omega)}^p \right]^{1/p}, \quad 1 \leq p < \infty,$$

$$\|V\|_{W_p^\infty(\Omega)} = \sup_{|\alpha| \leq k} \|D^\alpha V\|_{L^\infty(\Omega)}.$$

Adopt the following notations:

$$\|V\| = \|V\|_{L^2(\Omega)}, \quad |V| = \|V\|_{L^2(\partial\Omega)}, \quad \|V\|_k = \|V\|_{W_2^k(\Omega)}.$$

Set

$$(3) \quad H = \{v \in W_6^1(\Omega): \text{ for almost every } x \in \partial\Omega \text{ there is an open ball } B(x) \text{ about } x \text{ such that } v \in W_2^2(\Omega \cap B(x)), \text{ and such that } \partial v / \partial \nu \in L^2(\partial\Omega)\},$$

where $\partial v / \partial \nu$ denotes the derivative of v in the direction of the outward normal to $\partial\Omega$.

For each $h \in (0, 1)$ define a norm on H by

$$\| \! \| \varphi \| \! \| ^2 = \| \! \| \varphi \| \! \| _h^2 = \| \varphi \|_1^2 + h^{-1} |\varphi|^2 + h |\partial \varphi / \partial \nu|^2.$$

We shall consider a family $\{M_h\}_{0 < h \leq 1}$ of finite-dimensional subspaces of H satisfying the following assumptions:

(4i) There exists a positive integer r and a constant c_1 such that, if $2 \leq s \leq r + 1$ and $v \in H^s(\Omega)$, then

$$\inf_{\chi \in V_h} \{h \|v - \chi\|_h + h^2 \|v - \chi\|_{W_6^1(\Omega)}\} \leq c_1 h^s \|v\|_s.$$

(4ii) For each $v \in C_0^\infty(\Omega)$,

$$\inf \{ \|v - \chi\|_1 : \chi \in M_h, \text{ supp}(\chi) \subset\subset \Omega \} = o(1)$$

as h tends to zero.

(4iii) For all $\chi \in M_h$,

$$|\partial \chi / \partial \nu| \leq c_1 h^{-1/2} \|\chi\|_1.$$

The assumptions (4i)–(4iii) are satisfied by many finite element spaces that contain piecewise polynomials of degree r . The condition (4ii) is satisfied by almost all finite element spaces that satisfy (4i) with $o(1)$ replaced by $O(h^r)$; thus, it is a very mild constraint. Condition (4iii) is an inverse hypothesis on the family $\{M_h\}_{0 < h \leq 1}$; together with the hypothesis that $\partial\Omega$ is smooth, this condition effectively excludes tensor products of spaces of piecewise polynomials in a single variable. The conditions (4i) and (4iii) are needed for the analysis of Nitsche’s procedure even in the case in which the operator is linear, but the need for condition (4ii) is special to the nonlinear problem.

Let (\cdot, \cdot) and $\langle \cdot, \cdot \rangle$ denote the scalar products on $L^2(\Omega)$ and $L^2(\partial\Omega)$, respectively. For parameters $\gamma > 0$ and $z \in L^2(\Omega)$ define a bilinear form B on H by

$$(5) \quad B(z; v, w) = (a(z) \nabla v, \nabla w) - \left\langle a(g) \frac{\partial v}{\partial \nu}, w \right\rangle - \left\langle v, a(g) \frac{\partial w}{\partial \nu} - \gamma h^{-1} w \right\rangle, \quad v, w \in H,$$

where we have suppressed the writing of the x argument of a . Note that, if we use $z = v = u$, then B reduces to data in the sense that

$$(6) \quad B(u; u, w) = (f, w) - \left\langle g, a(g) \frac{\partial w}{\partial v} - \gamma h^{-1} w \right\rangle, \quad w \in H.$$

The following lemma is an easy consequence of the inverse hypothesis (4iii).

LEMMA 1 (NITSCHÉ). *There exist positive constants ρ and γ_0 , depending only on Ω, n, c_1, α_0 and α_1 , such that, if $\gamma \geq \gamma_0$,*

$$(7) \quad \rho \|v\|^2 \leq B(z; v, v), \quad v \in M_h, \quad z \in L^2(\Omega).$$

For each $\gamma > 0$ there exists $c_2 = c_2(\gamma, \alpha_1)$ such that

$$(8) \quad |B(z; v, w)| \leq c_2 \|v\| \|w\|, \quad v, w \in H, \quad z \in L^2(\Omega).$$

We shall assume henceforth that $\gamma \geq \gamma_0$ and is fixed; hence c_2 is also fixed and (7) holds.

Define an approximate solution u_h to be an element of M_h satisfying

$$(9) \quad B(u_h; u_h, w) = (f, w) - \left\langle g, a(g) \frac{\partial w}{\partial v} - \gamma h^{-1} w \right\rangle, \quad w \in M_h.$$

To see that there exists at least one solution u_h of (9) consider the map $S: M_h \rightarrow M_h$ defined by

$$(10) \quad B(y; Sy, w) = (f, w) - \left\langle g, a(g) \frac{\partial w}{\partial v} - \gamma h^{-1} w \right\rangle, \quad w \in M_h.$$

The condition (7) implies the nonsingularity of the finite set of linear equations that define S , and choosing $w = Sy$ in (10) shows that the range of S is contained in a ball. Since S is clearly continuous, the Brouwer fixed point theorem implies that (9) has a solution.

3. Convergence Result. Our main result for the procedure given by (9) is the following theorem.

THEOREM 1. *Suppose that, for some $\alpha \in (0, 1)$, $f \in C^\alpha(\bar{\Omega})$ and g can be extended to be in $C^{2+\alpha}(\bar{\Omega})$. Suppose also that $u \in W_2^s(\Omega)$ for some s satisfying $2 \leq s \leq r + 1$. Then there exists a constant c_3 such that for h sufficiently small*

$$(11) \quad \|u - u_h\| + h \|u - u_h\| \leq c_3 h^s.$$

Proof. Because of the finite dimensionality of the M_h 's the infimum in (4i) is actually assumed; let $\chi \in M_h$ be such that $\|u - \chi\| + h \|u - \chi\|_{W_{\frac{1}{6}}(\Omega)}$ is minimal. Note that (7), (9) and (5) imply that

$$\begin{aligned} \rho \|u_h - \chi\|^2 &\leq B(u_h; u_h - \chi, u_h - \chi) \\ &= B(u; u - \chi, u_h - \chi) + ((a(u) - a(u_h)) \nabla \chi, \nabla(u_h - \chi)) \\ &\leq (c_2 \|u - \chi\| + \|a(u) - a(u_h)\|_{L^3(\Omega)} \|\chi\|_{W_{\frac{1}{6}}(\Omega)}) \|u_h - \chi\|. \end{aligned}$$

Thus, by (4i) and the choice of χ ,

$$(12) \quad \|u_h - u\| \leq C [h^{s-1} + \|a(u) - a(u_h)\|_{L^3(\Omega)}].$$

Using the fact that a is uniformly Lipschitz continuous with respect to u and the interpolation result (since $\dim(\Omega) \leq 3$)

$$(13) \quad \|\varphi\|_{L^3(\Omega)} \leq C\|\varphi\|^{1/2}\|\varphi\|_1^{1/2},$$

we see that

$$(14) \quad \|u_h - u\| \leq C[h^{s-1} + \|u - u_h\|].$$

In order to bound $\|u - u_h\|$ we use a duality argument. Note that it follows directly from well-known elliptic regularity and Theorem 2 of [1] that any Dirichlet problem for the linear elliptic operator L defined in (2) has at most one weak solution in $W_2^1(\Omega)$. It then follows that for any $\zeta \in L^2(\Omega)$ there exists a unique $\varphi \in W_2^2(\Omega)$ such that

$$(15) \quad L^*\varphi = \zeta \quad \text{on } \Omega, \quad \varphi = 0 \quad \text{on } \partial\Omega,$$

where L^* is the formal adjoint of L :

$$L^*w = -\nabla \cdot (a(x, u)\nabla w) + a_u(x, u)\nabla u \cdot \nabla w.$$

Also there exists a constant C independent of ζ such that

$$(16) \quad \|\varphi\|_2 \leq C\|\zeta\|.$$

Take $\zeta = u - u_h$ in (15). A short computation shows that

$$(17) \quad \|\zeta\|^2 = (\zeta, L^*\varphi) = B(u; u, \varphi) - B(u_h; u_h, \varphi) + (\zeta \bar{a}_u \nabla \zeta - \bar{a}_{uu} \zeta^2 \nabla u, \nabla \varphi),$$

where

$$\bar{a}_u(x) = \int_0^1 a_u(x, u(x) - t\zeta(x)) dt,$$

$$\bar{a}_{uu}(x) = \int_0^1 (1 - t)a_{uu}(x, u(x) - t\zeta(x)) dt.$$

With $\chi \in M_h$ appropriately chosen we see from (17), (6), (9), (8), Hölder's inequality, the Sobolev imbedding theorem and (4i) (in that order) that

$$\begin{aligned} \|\zeta\|^2 &= B(u; u, \varphi - \chi) - B(u_h; u_h, \varphi - \chi) + (\zeta \bar{a}_u \nabla \zeta - \bar{a}_{uu} \zeta^2 \nabla u, \nabla \varphi) \\ &= B(u_h; \zeta, \varphi - \chi) + (\zeta \bar{a}_u \nabla u, \nabla(\varphi - \chi)) + (\zeta \bar{a}_u \nabla \zeta - \bar{a}_{uu} \zeta^2 \nabla u, \nabla \varphi) \\ &\leq C\|\zeta\| \|\varphi - \chi\| + C\|\zeta\|_{L^3(\Omega)} \|\zeta\| \|\varphi\|_{W^{1/6}(\Omega)} \\ &\leq C\|\zeta\| [h + \|\zeta\|_{L^3(\Omega)}] \|\varphi\|_2. \end{aligned}$$

Thus (16) and (13) imply that

$$\|\zeta\| \leq C\|\zeta\| [h + \|\zeta\|_{L^3(\Omega)}] \leq C[\|\zeta\| h + \|\zeta\|^{3/2} \|\zeta\|^{1/2}].$$

Hence,

$$(18) \quad \|\zeta\| \leq C[\|\zeta\| h + \|\zeta\|^3].$$

Using (14) in (18), we see that for h sufficiently small

$$(19) \quad \|\zeta\| + h\|\zeta\| \leq C[h^s + \|\zeta\|^3].$$

The inequality (19) proves the theorem provided we can show that $\|\xi\| \rightarrow 0$ as $h \rightarrow 0$; this is done via a compactness argument. From (12) and the fact that $|a(x, z)| \leq \alpha_1$ for $(x, z) \in \bar{\Omega} \times \mathbf{R}$ we see that there is a constant independent of h such that $\|u_h - u\| \leq C$. Hence

$$(20) \quad |u_h - g| \leq Ch^{1/2}$$

and

$$(21) \quad \|u_h\|_1 \leq C + \|u\|_1$$

From (21) we see that from any sequence of h 's tending to zero we can choose a subsequence $\{h_k\}_{k=1}^\infty$ such that for some $w \in W_2^1(\Omega)$, $u_{h_k} \rightarrow w$ in $L^2(\Omega)$ and weakly in $W_2^1(\Omega)$. It follows from (20) and the trace inequality

$$|\varphi| \leq C\|\varphi\|^{1/2}\|\varphi\|_1^{1/2}, \quad \varphi \in W_2^1(\Omega),$$

that

$$(22) \quad w = g \quad \text{on } \partial\Omega.$$

We want to show that $w = u$ by showing that w is a weak solution of (1). Take $v \in C_0^\infty(\Omega)$ and $v_{h_k} \in M_{h_k}$ such that v_{h_k} has compact support in Ω and

$$\|v - v_{h_k}\|_1 = o(1) \quad \text{as } k \rightarrow \infty.$$

Then

$$\begin{aligned} |(a(w)\nabla w, \nabla v) - (f, v)| &= |(a(w)\nabla w, \nabla(v - v_{h_k})) \\ &\quad + (a(w)\nabla w - a(u_{h_k})\nabla u_{h_k}, \nabla v_{h_k}) - (f, (v - v_{h_k}))| \\ &\leq C\|v - v_{h_k}\|_1 + |(a(w)\nabla w - a(u_{h_k})\nabla u_{h_k}, \nabla v)|. \end{aligned}$$

Rewriting the last term as

$$(a(w)\nabla(w - u_{h_k}), \nabla v) + ((a(w) - a(u_{h_k}))\nabla u_{h_k}, \nabla v)$$

and using the convergence of u_{h_k} to w , we see that

$$(23) \quad (a(w)\nabla w, \nabla v) = (f, v), \quad v \in C_0^\infty(\Omega).$$

Thus we see from (22) and (23) that w is a weak solution in $W_2^1(\Omega)$ of (1). Assume for the moment that such weak solutions are unique. Then $w = u$, and it follows by a standard argument that $u_h \rightarrow u$ in $L^2(\Omega)$ as $h \rightarrow 0$. Hence, $\|\xi\| \rightarrow 0$ as $h \rightarrow 0$, and the conclusion (11) follows from (19).

To show that weak solutions of (1) are unique we shall first use a "boot-strap" argument to see that weak solutions are smooth solutions and then apply the results of [1]. Suppose that $w \in W_2^1(\Omega)$ satisfies (22) and (23). Then by results of de Giorgi and Nash (see [2, Theorem 5.3.7]) w is in fact Hölder continuous on $\bar{\Omega}$. (We always choose the smooth element of the equivalence class in $W_2^1(\Omega)$ if there is one.) It then follows from a result of Morrey (see [2, Theorem 5.5.4]) that $w \in W_p^1(\Omega)$ for $1 < p < \infty$; in particular, $w \in W_4^1(\Omega)$. This then implies that $w \in W_2^2(\Omega)$, since w is a weak solution of

$$(24) \quad \begin{aligned} -\Delta\varphi &= (1/a)(\nabla a(\varphi)) \cdot \nabla\varphi + f \quad \text{on } \Omega, \\ \varphi &= g \quad \text{on } \partial\Omega. \end{aligned}$$

Finally we can apply the Schauder estimates (see [2, Theorem 5.6.3]) to see that $w \in C^{2+\alpha}(\bar{\Omega})$. Thus, weak solutions of (1) are in fact classical solutions of (1) and belong to $C^2(\bar{\Omega})$; therefore, Theorem 1 of [1] implies that these solutions are unique. This completes the proof of Theorem 1.

4. Newton's Method. Using an additional hypothesis on the function spaces M_h , we shall find conditions under which Newton's method can be used to compute the solutions u_h of the nonlinear algebraic equations (9).

For $z \in L^2(\Omega)$ define a bilinear form $N(z; \cdot, \cdot)$ on H by

$$(25) \quad N(z; v, w) = B(z; v, w) + D(z; v, w),$$

where B is defined in (5) and

$$(26) \quad D(z; v, w) = (a_u(z)v\nabla z, \nabla w).$$

Given $z_0 \in M_h$, the Newton approximations to u_h form a sequence $\{z_k\}_{k=0}^\infty$ in M_h satisfying

$$(27) \quad N(z_k; z_{k+1} - z_k, v) = (f, v) - \left\langle g, a(g) \frac{\partial v}{\partial \nu} - \gamma h^{-1} v \right\rangle - B(z_k; z_k, v), \quad v \in M_h.$$

For each M_h let

$$(28) \quad \sigma_h = \sup \{ \|v\|_{L^\infty(\Omega)} / \|v\|_1 : 0 \neq v \in M_h \}.$$

We shall assume throughout this section that u_h converges to u sufficiently rapidly that

$$(29) \quad \|u - u_h\|_{L^\infty(\Omega)} + \sigma_h \|u - u_h\|_1 \rightarrow 0 \quad \text{as } h \rightarrow 0.$$

In addition, we shall assume that there is a constant c_4 independent of h , such that

$$(30) \quad \|u_h\|_{W_\infty^1(\Omega)} \leq c_4;$$

in many cases this can be verified by using Theorem 1 together with approximation and inverse assumptions which are slightly stronger than those made in (4).

Our main result for Newton's method is the following.

THEOREM 2. *There exist positive constants h_0, δ and c_5 such that, if $0 < h \leq h_0$ and $\sigma_h \|z_0 - u_h\|_1 \leq \delta$, then $\{z_k\}_{k=0}^\infty$ exists and $\nu_k = \|z_k - u_h\|_1$ is a decreasing sequence satisfying*

$$(*) \quad \nu_{k+1} \leq c_5 \sigma_h \|z_k - u_h\|_1^2 \leq c_5 \sigma_h \nu_k^2.$$

The proof of Theorem 2 relies heavily on the following lemma.

LEMMA 2. *Given $\tau > 0$, there exist positive constants δ, h_0 and c_6 such that the following holds. If $0 < h \leq h_0$, if $z \in W_\infty^1(\Omega)$ satisfies*

$$\|z\|_{W_\infty^1(\Omega)} \leq \tau \quad \text{and} \quad \|z - u\|_1 \sigma_h \leq \delta,$$

and if G is a linear functional on H with norm $\|G\|$, then there exists a unique $v \in M_h$ satisfying the equations

$$(31) \quad N(z; v, w) = G(w), \quad w \in M_h.$$

Furthermore, v satisfies the bound

$$(32) \quad \|v\| \leq c_6 \|G\|.$$

Proof. It suffices to show that (32) holds, since it implies that solutions of (31) are unique and hence exist.

From Lemma 1 it follows that

$$\begin{aligned} \rho \|v\|^2 &\leq B(z; v, v) = G(v) - D(z; v, v) \\ &\leq [\|G\| + \|a_u(z) \nabla z\|_{L^\infty(\Omega)} \|v\|] \|v\|. \end{aligned}$$

Hence,

$$(33) \quad \|v\| \leq \tilde{C} [\|G\| + \|v\|].$$

Let L^* be as in (15), and let φ satisfy

$$L^* \varphi = v \quad \text{on } \Omega, \quad \varphi = 0 \quad \text{on } \partial\Omega.$$

Then, for $\chi \in M_h$,

$$(34) \quad \begin{aligned} \|v\|^2 &= N(u; v, \varphi) \\ &= \{N(z; v, \varphi - \chi) + G(\varphi + (\chi - \varphi))\} + [N(u; v, \varphi) - N(z; v, \varphi)]. \end{aligned}$$

Using (4i) and the bound $\|\varphi\|_2 \leq C\|v\|$, we see that

$$(35) \quad \{\cdot \cdot \cdot\} \leq C(h\|v\| + \|G\|)\|v\|.$$

A short computation shows that

$$(36) \quad \begin{aligned} [\cdot \cdot \cdot] &\leq C\|u - z\|_{L^\infty(\Omega)} \|v\|_1 \|\varphi\|_1 + C\|v\|_{L^\infty(\Omega)} \|u - z\|_1 \|\varphi\|_1 \\ &\leq C(\|u - u_h\|_{L^\infty(\Omega)} + \sigma_h(\|u - u_h\|_1 + \|u_h - z\|_1)) \|v\|_1 \|v\|. \end{aligned}$$

Thus (34), (35) and (36) imply that

$$(37) \quad \|v\| \leq C\|G\| + F\|v\|,$$

where

$$F = C(h + \|u - u_h\|_{L^\infty(\Omega)} + \sigma_h(\|u - u_h\|_1 + \|u_h - z\|_1)).$$

From (33) and (37) it follows that

$$(38) \quad (1 - \tilde{C}F)\|v\| \leq C\|G\|.$$

If h_0 and δ are taken sufficiently small that $\tilde{C}F \leq 1/2$, then (38) implies (32). This completes the proof of the lemma.

Proof of Theorem 2. First we show that, if h_0 and δ are sufficiently small, if $0 < h \leq h_0$, and if $\sigma_h \|z_k - u_h\| \leq \delta$, then there exists a unique z_{k+1} . It suffices to show that, if $v \in M_h$ satisfies

$$N(z_k; v, w) = 0, \quad w \in M_h,$$

then $v \equiv 0$. To see this, note that

$$N(u_h; v, w) = G(w), \quad w \in M_h,$$

where

$$G(w) = ([a(u_h) - a(z_k)] \nabla v, \nabla w) + ([a(u_h) - a(z_k)] \nabla u_h - a(z_k) \nabla(z_k - u_h))v, \nabla w).$$

It is easily checked that $\|G\| \leq C\sigma_h \|u_h - z_k\|_1 \|v\|_1$. Hence, by Lemma 2, $\|v\| \leq c_6 C\sigma_h \|u_h - z_k\|_1 \|v\|$; thus, $v \equiv 0$ if $c_6 C\delta < 1$.

To verify (*), note that

$$\begin{aligned} N(u_h; z_{k+1} - u_h, w) &= N(u_h; z_k - u_h, w) + N(z_k; z_{k+1} - z_k, w) \\ &\quad + [N(u_h; z_{k+1} - z_k, w) - N(z_k; z_{k+1} - z_k, w)] \\ (39) \qquad \qquad \qquad &= \{N(u_h; z_k - u_h, w) + B(u_h; u_h, w) - B(z_k; z_k, w)\} \\ &\quad + [N(u_h; z_{k+1} - z_k, w) - N(z_k; z_{k+1} - z_k, w)] \\ &= G_1(w) + G_2(w) = G(w), \quad w \in M_n, \end{aligned}$$

where the braces and brackets indicate the decomposition of G into G_1 and G_2 . Since

$$G_1(w) = (\frac{1}{2}\tilde{a}_{uu}(z_k - u_h)^2 \nabla u_h + \tilde{a}_u(z_k - u_h) \nabla(u_h - z_k), \nabla w),$$

where \tilde{a}_{uu} and \tilde{a}_u are certain averages of a_{uu} and a_u , respectively, it follows that

$$(40) \qquad \qquad \qquad \|G_1\| \leq C\sigma_h \|z_k - u_h\|_1^2 \leq C\sigma_h \nu_k^2.$$

Similarly, since

$$\begin{aligned} G_2(w) &= ([a(u_h) - a(z_k)] \nabla(z_{k+1} - z_k), \nabla w) \\ &\quad + ([a_u(u_h) - a_u(z_k)] \nabla u_h + a_u(z_k) \nabla(u_h - z_k))(z_{k+1} - z_k), \nabla w), \end{aligned}$$

we see that

$$\begin{aligned} (41) \qquad \qquad \qquad \|G_2\| &\leq C\sigma_h \|z_k - u_h\|_1 (\|z_k - u_h\|_1 + \|z_{k+1} - u_h\|_1) \\ &\leq C\sigma_h \nu_k (\nu_k + \nu_{k+1}). \end{aligned}$$

The conclusion, (*), then follows from Lemma 2, (39), (40), and (41).

In the cases where M_n is obtained from piecewise polynomial functions over a quasi-regular triangulation of Ω , one can show that

$$\sigma_h \approx \ln h^{-1}, \quad n = 2, \quad \text{or} \quad \sigma_h \approx h^{-\frac{1}{2}}, \quad n = 3.$$
