Asymptotic Behavior of Vector Recurrences with Applications

By Alan Feldstein and J. F. Traub*

Abstract. The behavior of the vector recurrence $y_{n+1} = My_n + w_{n+1}$ is studied under very weak assumptions. Let $\lambda(M)$ denote the spectral radius of M and let $\lambda(M) \geq 1$. Then if the w_n are bounded in norm and a certain subspace hypothesis holds, the root order of the y_n is shown to be $\lambda(M)$. If one additional hypothesis on the dimension of the principal Jordan blocks of M holds, then the quotient order of the y_n is also $\lambda(M)$. The behavior of the homogeneous recurrence is studied for all values of $\lambda(M)$.

These results are applied to the analysis of

(1) Nonlinear iteration with application to iteration with memory and to parallel iteration algorithms.

(2) Order and efficiency of composite iteration.

1. Introduction. We study the behavior of the vector recurrence

(1) $$y_{n+1} = My_n + w_{n+1}$$

under very weak assumptions. We apply our results to the analysis of iterations for nonlinear equations and to the composition of such iterations. In particular our results can be used to study one-point iterations with memory and iterations for solving nonlinear equations on parallel computers. An extended discussion of applications, including use of the power method to calculate the spectral radius, may be found in Feldstein and Traub [74].

Let $\|\cdot\|$ denote any convenient vector norm or the induced matrix norm. When the following limits exist, define the *root order* by

$$R(y_n) = \lim_{n \to \infty} \|y_n\|^{1/n}$$

and the *quotient order* by

$$Q(y_n) = \lim_{n \to \infty} \frac{\|y_{n+1}\|}{\|y_n\|} .$$

Clearly, if the quotient order exists, then so does the root order (though not conversely), and they are equal.

Let U be a nonsingular matrix such that $M = U^{-1}JU$, where J is the direct sum of K Jordan block matrices, $J = J_1 \oplus J_2 \oplus \cdots \oplus J_K$. Let λ_k be the eigenvalue corresponding to J_k and let the dimension of J_k be D_k. Let the K Jordan blocks of J be arranged so that

$$\begin{cases} |\lambda_1| \geqslant |\lambda_2| \geqslant \cdots \geqslant |\lambda_K|, \text{ and} \\ |\lambda_1| = |\lambda_2| = \cdots = |\lambda_L| \quad \text{implies } D_1 \geqslant D_2 \geqslant \cdots \geqslant D_L. \end{cases}$$

$J_1, J_2, \ldots, J_L$ are called the *principal Jordan blocks* of M. Denote $D = D_1$, and $\lambda = \lambda_1$. Thus $|\lambda|$ is the spectral radius of M, which we shall sometimes write as $\lambda(M)$.

In order to draw the conclusions which follow we must assume that the initial vector y_0 does not lie in a certain subspace. Since the statement of this hypothesis is given in Eq. (16) and involves certain quantities not defined until Section 5, we find it convenient to label this as the "subspace hypothesis". We now state our main result; the proof is given in Section 5.

THEOREM 1. *Assume $\lambda(M) \geqslant 1$ and*

1. $\|w_n\| \leqslant w < \infty$ *for all n,*
2. *"Subspace hypothesis".*

Then

(i) $R(y_n) = \lambda(M)$.

If, in addition,

3. $D_k < D$ *for $2 \leqslant k \leqslant L$, when $|\lambda_k| = |\lambda|$ with $\lambda_k \neq \lambda$, then*

(ii) $Q(y_n) = \lambda(M)$.

Herzberger [74] has independently analyzed the order of (1). However, his assumptions are far more restrictive than ours. Of course there are important applications of (1) where Herzberger's conditions hold. In our terminology Herzberger's main result may be stated as

THEOREM 1'. *Assume*

1. $\lim_{n \to \infty} w_n = w < \infty$,
2. $\lambda(M) > 1$,
3. *M is a nonnegative matrix,*
4. *M is primitive (see Varga [62]).*

Then

$$R(y_n) = Q(y_n) = \lambda(M).$$

Because of his strong conditions, Herzberger does not need to distinguish between the existence of root and quotient order. Herzberger does not include a subspace hypothesis although we believe one to be necessary.

The example $y_{n+1} = \lambda y_n + w$, $\lambda < 1$, $w \neq 0$, shows that Theorem 1 need not hold if $\lambda < 1$. However the conclusions of Theorem 1 hold for all values of λ if we restrict ourselves to homogeneous recurrences, $w_n = 0$ for all n. In this case (1) becomes $y_{n+1} = My_{n+1}$, the y_n are the iterates of the power method and we have

THEOREM 2. *Assume*

1. $w_n = 0$ *for all n.*

If $\lambda(M) = 0$,

      (i) $R(\mathbf{y}_n) = \lambda(M)$.

If $\lambda(M) > 0$ *and if*

      (2) *"Homogeneous subspace hypothesis", then*

      (ii) $R(\mathbf{y}_n) = \lambda(M)$.

If, in addition,

      3. $D_k < D$ *for* $2 \leqslant k \leqslant L$, *when* $|\lambda_k| = \lambda$ *with* $\lambda_k = \lambda$, *then*

      (iii) $Q(\mathbf{y}_n) = \lambda(M)$.

      Observe that if $\lambda(M) = 0$, then no subspace condition is required. If $\lambda(M) > 0$, then the homogeneous subspace hypothesis is the classical condition that the initial vector $\mathbf{y}_0$ may not be an eigenvector corresponding to a subdominant eigenvalue. In the notation of this paper the *homogeneous* subspace hypothesis is (16) with $\mathbf{f} = \mathbf{0}$ and $\delta = 1$ for *all* λ (even $|\lambda| = 1$).

      We summarize the rest of this paper. Applications are considered in the next two sections while the proof of the main theorem is deferred until the last two sections. Readers interested primarily in the proof should turn first to Section 4. Section 2 discusses the matrix representation of nonlinear iteration and utilizes the representation in the analysis of parallel algorithms. New results on the order and efficiency of composite iteration are analyzed in Section 3. The main result is proved in Section 4. Proofs of estimates needed in the proof of the main theorem may be of independent interest and appear in Section 5.

2. Matrix Representation of Nonlinear Iteration: Applications to Iteration With Memory and to Parallel Algorithms.

Let a sequence of vectors $\{\mathbf{x}_n\}$ be generated by the vector-valued function $\varphi: R^N \longrightarrow R^N$ and

$$(2) \qquad\qquad\qquad \mathbf{x}_{n+1} = \varphi(\mathbf{x}_n).$$

Assume that at least one component of $\mathbf{x}_n$ converges to at least one component of the constant vector α. Let the components of $\mathbf{x}_n$, $\mathbf{y}_n$, and α be labelled $x_{n,j}$, $y_{n,j}$, and α_j. Let

$$y_{n,j} = \log |x_{n,j} - \alpha_j|.$$

Then $\|\mathbf{y}_n\| \longrightarrow \infty$ as $n \longrightarrow \infty$. For many important problems, the vectors $\mathbf{y}_n$ satisfy (1). Examples are given below. We then call (1) the *logarithmic error equation* (or simply the *error equation*) for the sequence $\{\mathbf{x}_n\}$ and call M the *matrix representation* of the iteration function φ.

      If (1) is the error equation of (2), we define the *root order* of φ as

$$R(\varphi) = R(\mathbf{y}_n)$$

and the *quotient order* of φ as

$$Q(\varphi) = Q(\mathbf{y}_n).$$

      The important idea of matrix representation of nonlinear iteration is due to

Rice [71]. His matrix representation seems unnecessarily complicated. Rice's analysis does not distinguish between root and quotient order.

The following example shows applications of this formulation.

Example 1. Assume that α is a zero of a scalar function g. One-point iterations with memory are of the form (Traub [64], Feldstein and Firestone [67] and [69], Hindmarsh [72])

$$(3) \qquad z_{n+1} = \varphi(z_n, z_{n-1}, \ldots, z_{n-N+1})$$

with errors satisfying

$$(4) \qquad z_{n+1} - \alpha = c_{n+1}(z_n - \alpha)^{b_1} \cdots (z_{n-N+1} - \alpha)^{b_N},$$

where the b_i are nonnegative integers.

Equation (3) may be written as

$$(5) \qquad \begin{cases} x_{n+1,1} = \varphi(x_{n,1}, \ldots, x_{n,N}), \\ x_{n+1,j} = x_{n,j-1} \quad \text{for } j = 2, 3, \ldots, N. \end{cases}$$

Let all components of $\boldsymbol{\alpha}$ be α. One easily shows that the error $\mathbf{y}_{n+1}$ satisfies

$$\mathbf{y}_{n+1} = M\mathbf{y}_n + \mathbf{w}_{n+1} \quad \text{where}$$

$$(6) \qquad M = \begin{pmatrix} b_1 & b_2 & \cdots & b_{N-1} & b_N \\ 1 & 0 & & & \\ 0 & 1 & & & \\ \cdot & & \cdot & & \\ \cdot & & & \cdot & \\ \cdot & & & & \cdot \\ 0 & 0 & & 1 & 0 \end{pmatrix}, \qquad \mathbf{w}_{n+1} = \begin{pmatrix} \log|c_{n+1}| \\ 0 \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \end{pmatrix}.$$

Observe that M is the companion matrix for the indicial polynomial of the linear recurrence.

Conclusions (i) and (ii) of Theorem 1 hold for all Hermite interpolatory iteration functions. The quotient order was first established by Traub [64] for the equal information case $b_1 = b_2 = \cdots = b_N$ and by Feldstein and Firestone [67] for arbitrary nonnegative integers $b_1, \ldots, b_N$ using recurrence equation techniques.

A number of authors (Feldstein and Firestone [67], Shedler [67], Miranker [69] and Rice [71]) have studied the use of parallel computers to calculate a zero of a scalar function. Most of the proposed iterations have the form

$$x_{n+1,i} = \varphi_i(x_{n,1}, \ldots, x_{n,N}) \quad \text{for } i = 1, \ldots, N,$$

where N is the number of processors. Assume the errors satisfy

$$x_{n+1,i} - \alpha = c_{n,i} \prod_{j=1}^{N} (x_{n,j} - \alpha)^{m_{i,j}}.$$

Then the error equation (1) holds with

$$\mathbf{w}_n = (\log|c_{n,1}|, \ldots, \log|c_{n,N}|)^T$$

and with the elements of M given by $(m_{i,j})$. See Examples 3 and 5 of Feldstein and Traub [74] for more details.

3. Composition and Efficiency. We turn to the order of a *composite* iteration. Suppose that

$$\mathbf{x}_{n+1}^{(1)} = \varphi_1(\mathbf{x}_n^{(1)}), \quad \mathbf{x}_{n+1}^{(2)} = \varphi_2(\mathbf{x}_n^{(2)}).$$

Then the composite iteration is $\psi = \varphi_2 \circ \varphi_1$, where $\psi: R^N \rightarrow R^N$, and the composite iteration sequence $\{\mathbf{x}_n\}$ is defined by

$$\mathbf{x}_{n+1} = \psi(\mathbf{x}_n) \equiv \varphi_2(\varphi_1(\mathbf{x}_n)).$$

Let φ_1 and φ_2 have characteristic matrices M_1 and M_2 with logarithmic error equations

$$\mathbf{y}_{n+1}^{(1)} = M_1\mathbf{y}_n^{(1)} + \mathbf{w}_{n+1}^{(1)}, \quad \mathbf{y}_{n+1}^{(2)} = M_2\mathbf{y}_n^{(2)} + \mathbf{w}_{n+1}^{(2)}.$$

Let $M = M_2 M_1$ and $\mathbf{w}_{n+1} = M_2\mathbf{w}_{n+1}^{(1)} + \mathbf{w}_{n+1}^{(2)}$. Then ψ has the error equation $\mathbf{y}_{n+1} = M\mathbf{y}_n + \mathbf{w}_{n+1}$. See Example 6 of Feldstein and Traub [74] for specific representations of composite algorithms.

In the following theorem the use of $D, D_k, \lambda, \lambda_k$ and the subspace hypotheses all refer to the matrix $M = M_2 M_1$. We state the main Composition Theorem. Its proof is an immediate consequence of Theorem 1.

THEOREM 3. *Assume*
  1. $\|\mathbf{w}_{n+1}\| \leqslant w < \infty$ *for all* n,
  2. *"Subspace Hypothesis"*,
  3. $\lambda(M_2 M_1) \geqslant 1$.
Then

$$R(\varphi_2 \circ \varphi_1) = \lambda(M_2 M_1).$$

If, in addition,
  4. $D_k < D$ *for* $2 \leqslant k \leqslant L$, *when* $|\lambda_k| = |\lambda|$ *with* $\lambda_k \neq \lambda$, *then*

$$Q(\varphi_2 \circ \varphi_1) = \lambda(M_2 M_1).$$

Observe that a composite algorithm may have an order of convergence either less than, equal to, or greater than the product of the orders of the individual algorithms. See Example 7 of Feldstein and Traub [74] for details. It is easy to see that

COROLLARY 1. *Order is invariant under commuting of two compositions.*

Observe that Corollary 1 is false for three compositions, because $\lambda(M_1 M_2 M_3)$ need not equal $\lambda(M_3 M_2 M_1)$.

From Corollary 1, order multiplies under self-composition. Another important case for which order multiplies under composition is when φ is a scalar one-point iteration (Traub [64, Chapter 2]). *In general, order does not multiply under*

composition even in the case of scalar φ. This was first shown by Hindmarsh [72] who used difference equation techniques in his analysis, and by Rice [71] using matrix representation techniques.

To compare iterations it is useful to have the concept of an *efficiency measure.* See Kung and Traub [74] and Traub and Woźniakowski [76]. Let $c(\varphi) > 0$ be some "cost" associated with computing x_{n+1} from x_n. The efficiency index of φ is defined, for $p > 1$, by

$$e(\varphi) = (\log p(\varphi))/c(\varphi)$$

We wish to compare the efficiency of the composite iteration $\varphi_2 \circ \varphi_1$ with the efficiencies of φ_1 and φ_2. In the following discussion we do not distinguish between root and quotient order; both are represented by $p(\varphi)$. We denote $p_i = p(\varphi_i)$, $p_{i,j} = p(\varphi_i \circ \varphi_j)$, $c_{i,j} = c(\varphi_i \circ \varphi_j)$, $e_{i,j} = e(\varphi_i \circ \varphi_j)$. We assume that $c_{1,2} = c_{2,1}$. Then by Corollary 1, $e_{1,2} = e_{2,1}$. It is reasonable to assume that $c_{2,1} \leqslant c_1 + c_2$. In the following theorem assume that $p_1 = \lambda(M_1)$, $p_2 = \lambda(M_2)$, and $p_{2,1} = \lambda(M_2 M_1)$. The hypotheses of Theorems 1 and 3 are sufficient to guarantee this. We omit the proof which is straightforward.

THEOREM 4. 1. *Let* $c_{2,1} = c_1 + c_2$.

(a) *If* $\lambda(M_2 M_1) > \lambda(M_2)\lambda(M_1)$, *then* $\min(e_1, e_2) < e_{2,1}$.

(b) *If* $\lambda(M_2 M_1) = \lambda(M_2)\lambda(M_1)$, *then* $\min(e_1, e_2) \leqslant e_{2,1} \leqslant \max(e_1, e_2)$.

(c) *If* $\lambda(M_2 M_1) < \lambda(M_2)\lambda(M_1)$, *then* $e_{2,1} < \max(e_1, e_2)$.

2. *On the other hand, let* $c_{2,1} < c_1 + c_2$.

If $\lambda(M_2 M_1) \geqslant \lambda(M_2)\lambda(M_1)$, *then* $\min(e_1, e_2) < e_{2,1}$.

It is possible that the efficiency of a composite iteration may be greater than the *maximum efficiencies* of the component iterations, i.e.,

(7a) $$e_{2,1} > \max(e_1, e_2).$$

In view of Theorem 4 this can *only* happen if either of the following conditions holds:

(7b) $$c_{2,1} < c_1 + c_2$$

or

(7c) $$\lambda(M_2 M_1) > \lambda(M_2) \cdot \lambda(M_1).$$

Example 9 of Feldstein and Traub [74] shows a situation where (7a, b, c) all hold.

We can easily calculate sufficient conditions for (7a) to hold. For example, assume that $c_{2,1} = c_1 + c_2$ and that (7c) holds. Let

$$\eta = \log \lambda(M_2 M_1) - \log \lambda(M_2) - \log \lambda(M_1) > 0.$$

Then $e_{2,1} > \max(e_1, e_2)$ if

$$\eta > c_1(e_2 - e_1) \quad \text{for } e_2 > e_1, \quad \text{or} \quad \eta > c_2(e_1 - e_2) \quad \text{for } e_2 < e_1.$$

In general we are interested in iterations such that η and $\mu = c(\varphi_1) + c(\varphi_2) - c(\varphi_2 \circ \varphi_1)$ are positive and as large as possible. How to do this is an open question.

4. Proof of The Main Theorem. The proof of Theorem 1 uses certain estimates (Lemmas 1 and 2, below) on the growth as $n \longrightarrow \infty$ of each block J_k^n for $1 \leqslant k \leqslant K$. Since the proofs of these lemmas are rather long and since these lemmas may be of independent interest, we defer the proofs until Section 5 and confine ourselves here to a statement of the results needed for the proof of Theorem 1. We shall start from Eq. (1), written here for notational convenience with primes as

$$\mathbf{y}'_{n+1} = M\mathbf{y}'_n + \mathbf{w}'_{n+1}.$$

Write M in the Jordan form $M = U^{-1}JU$. Let

$$\mathbf{y}_n = U\mathbf{y}'_n \quad \text{and} \quad \mathbf{w}_n = U\mathbf{w}'_n.$$

Then

$$\mathbf{y}_{n+1} = J\mathbf{y}_n + \mathbf{w}_{n+1}.$$

Let $C(a, b)$ denote a binomial coefficient. Let $\mathbf{w}_{n,k}$ be that portion of the vector $\mathbf{w}_n$ which is associated with the Jordan block J_k. Let

$$(8) \qquad \delta = \begin{cases} 0 & \text{if } |\lambda| = 1, \\ 1 & \text{otherwise,} \end{cases}$$

$$(9) \qquad Q_{n,k} = J_k^n / (\lambda^n C(n, D - \delta)),$$

$$(10) \qquad \mathbf{s}_{n,k} = \sum_{i=0}^{n} J_k^i \mathbf{w}_{n-i,k}.$$

When the limit exists (see Eqs. (28) and (30)), define

$$\mathbf{f}_k(z) = \lim_{n \to \infty} \sum_{i=0}^{n-D} z^i \frac{C(n - i, D - 1)}{C(n, D - \delta)} \mathbf{w}_{i,k}.$$

If $\|\mathbf{w}_n\| < w < \infty$ for all n, then we will show (30) that this limit exists and indeed that $\mathbf{f}_k(z)$ is analytic for $|z| \leqslant |\lambda^{-1}|$.

For $1 \leqslant k \leqslant K$ let W_k be the $D_k \times D_k$ matrix having ones on the superdiagonal and zeros elsewhere. Then $W_k^j = 0$ for $j \geqslant D_k$ and $W_k^{D_k - 1}$ is a matrix with a one in the upper right-hand corner and zeros elsewhere. If $D_k = 1$, define $W_k = 0$, $W_k^{D_k - 1} = 1$. Usually the subscript of W_k will be clear from context, and we will simply write W. The symbol $O(n^{-1})$ will denote a scalar, a vector, or a matrix (according to context) each of whose entries is bounded in absolute value by n^{-1} times some nonnegative constant.

LEMMA 1. *Let* $\lambda(M) > 0$. *The following hold for* $1 \leqslant k \leqslant K$:

1. *If* $|\lambda_k| < |\lambda|$, *then* $Q_{n,k} = O(n^{-1})$.
2. *If* $D_k \leqslant D - 1$, *then* $Q_{n,k} = O(n^{-1})$.
3. *If* $D_k = D$ *and* $|\lambda_k| = |\lambda|$, *then*

$$Q_{n,k} = \delta (\lambda_k/\lambda)^n \lambda_k^{1-D} W^{D-1} + O(n^{-1}).$$

LEMMA 2. *Let $\lambda(M) \geqslant 1$ and $\|w_n\| \leqslant w < \infty$ for all n. The following hold for $1 \leqslant k \leqslant K$:*

1. *If $|\lambda_k| < |\lambda|$, then $s_{n,k}/(\lambda^n C(n, D - \delta)) = O(n^{-1})$.*

2. *If $D_k \leqslant D - 1$, then $s_{n,k}/(\lambda^n C(n, D - \delta)) = O(n^{-1})$.*

3. *If $|\lambda_k| = |\lambda|$ and $D_k = D$, then*

$$s_{n,k}/(\lambda^n C(n, D - \delta)) = (\lambda_k/\lambda)^n \lambda_k^{1-D} W^{D-1} f_k(\lambda_k^{-1}) + O(n^{-1}),$$

$$\lim_{n\to\infty} \|s_{n,k}/(\lambda^n C(n, D - \delta))\| = |\lambda_k|^{1-D} \|W^{D-1} f_k(\lambda_k^{-1})\|.$$

Furthermore, $f_k(z)$ is analytic for $|z| \leqslant |\lambda^{-1}|$.

Remark. In part 3 of Lemmas 1 and 2 notice that $\lim_{n\to\infty}(\lambda_k/\lambda)^n$ exists if and only if $\lambda_k = \lambda$. Hence the following limit results hold if and only if $\lambda_k = \lambda$:

$$\lim_{n\to\infty} Q_{n,k} = \delta \lambda_k^{1-D} W^{D-1}, \qquad \lim_{n\to\infty} s_{n,k}/(\lambda^n C(n, D - \delta)) = \lambda_k^{1-D} W^{D-1} f_k(\lambda_k^{-1}).$$

This point is the important key to hypothesis 3 which distinguishes between the root and quotient order results of Theorems 1 and 2, because in order for the quotient order result to hold, the limits above must hold. See also Eq. (17). □

We now prove Theorem 1. Start from (1) in Jordan form

$$(11) \qquad\qquad y_{n+1} = Jy_n + w_{n+1}.$$

Let $y_{n,k}$ and $w_{n,k}$ be the portions of the vectors y_n and w_n corresponding to the Jordan block J_k. It may be easily verified from Eqs. (10) and (11) that

$$(12) \qquad\qquad y_{n,k} = J_k^n y_{0,k} + s_{n,k},$$

where $s_{n,k}$ was given by (10). Let

$$(13) \qquad\qquad v_{n,k} = y_{n,k}/(\lambda^n C(n, D - \delta)).$$

Substitute (12) and (9) into (13). Then

$$(14) \qquad\qquad v_{n,k} = Q_{n,k} y_{0,k} + s_{n,k}/(\lambda^n C(n, D - \delta)).$$

Since $\|w_n'\|$ is bounded by hypothesis and U is a nonsingular matrix, $\|w_n\|$ is also bounded. Lemmas 1 and 2 may be applied. Parts 1 and 2 of the lemmas clearly show that we need to consider only those components for which $|\lambda_k| = |\lambda|$ and $D_k = D$ both hold, for otherwise $v_{n,k} \to 0$. Apply part 3 of Lemmas 1 and 2 to those components to obtain

$$(15) \qquad\qquad v_{n,k} = (\lambda_k/\lambda)^n \lambda_k^{1-D} W_k^{D-1} \{\delta y_{0,k} + f_k(\lambda_k^{-1})\} + O(n^{-1}).$$

We are now ready to define the *subspace hypothesis* which is hypothesis 2 in Theorems 1, 2, and 3:

$$(16) \quad W_k^{D-1} \{\delta y_{0,k} + f_k(\lambda_k^{-1})\} \neq 0 \quad \text{for some } k \text{ such that } |\lambda_k| = |\lambda| \text{ and } D_k = D.$$

(Recall that $y_{0,k}$ and f_k in (16) come from the *Jordan transform* of (1). Recall also that, in Theorem 2, $f_k = 0$ and $\delta = 1$, *always*.) Note (16) implies that the full vector

$\mathbf{v}_n$ has at least one component which, as $n \rightarrow \infty$ is bounded away from zero (recall that $|\lambda_k| = |\lambda| \neq 0$). By (13), the same is true for the vector $\mathbf{y}_n$ and thus also for $\mathbf{y}_n'$.

Since $\delta = 0$ when $\lambda(M) = 1$, the subspace hypothesis becomes

$$W_k^{D-1} \mathbf{f}_k(\lambda_k^{-1}) \neq 0$$

for some k such that $|\lambda_k| = 1$ and $D_k = D$. There are many nontrivial situations that yield $\mathbf{f}_k(\lambda^{-1}) = 0$. In such cases Theorem 1 cannot be applied although $R(\mathbf{y}_n) = 1$ and $Q(\mathbf{y}_n) = 1$ may still hold. We shall not pursue this in the present paper.

To establish the root order result, take norms in (15).

$$\|\mathbf{v}_{n,k}\| \leq |\lambda|^{1-D} \|W\|^{D-1} \{\delta \|\mathbf{y}_{0,k}\| + \|\mathbf{f}_k(\lambda_k^{-1})\|\} + O(n^{-1}).$$

Thus $\mathbf{v}_n$ is bounded in norm. Since $C(n, D - \delta)/n^{D-\delta} \rightarrow 1/(D - \delta)!$ as $n \rightarrow \infty$, then

$$\mathbf{y}_n' = U^{-1} \mathbf{y}_n = \lambda^n n^{D-\delta} \mathbf{v}_n'$$

for some vector $\mathbf{v}_n'$ which is bounded in norm and which by application of the subspace hypotheses is bounded away from zero for n sufficiently large. Therefore,

$$\|\mathbf{y}_n'\|^{1/n} = |\lambda| n^{(D-\delta)/n} \|\mathbf{v}_n'\|^{1/n} \rightarrow |\lambda| \quad \text{as } n \rightarrow \infty.$$

Hence $R(\mathbf{y}_n') = \lambda(M)$.

To establish the quotient order result, we need to consider only $k = 1$ (by the hypotheses of Theorem 1 and by Lemmas 1 and 2). Since $\lambda_1 = \lambda$, then Eq. (15) becomes (see the Remark following Lemma 2)

$$(17) \qquad \mathbf{v}_{n,1} = \lambda^{1-D} W^{D-1} \{\delta \mathbf{y}_{0,1} + \mathbf{f}_1(\lambda^{-1})\} + O(n^{-1}).$$

An application of the subspace hypothesis shows that $\mathbf{v}_{n,1}$ has a nonzero limit as $n \rightarrow \infty$. Thus there is some vector $\mathbf{v}_n'$, with a nonzero limit, for which

$$\mathbf{y}_n' = \lambda^n n^{D-\delta} \mathbf{v}_n',$$

$$\frac{\|\mathbf{y}_{n+1}'\|}{\|\mathbf{y}_n'\|} = |\lambda| \left(\frac{n+1}{n}\right)^{D-\delta} \frac{\|\mathbf{v}_{n+1}'\|}{\|\mathbf{v}_n'\|} \rightarrow |\lambda| \quad \text{as } n \rightarrow \infty.$$

Hence $Q(\mathbf{y}_n') = \lambda(M)$ which completes the proof of Theorem 1. $\square$

The proof of Theorem 2 is a minor modification of the proof of Theorem 1, with $\mathbf{s}_{n,k} = \mathbf{0}$, and is omitted.

5. Proofs of the Lemmas. The statements of Lemmas 1 and 2 were given in Section 4 and will not be repreated here. Fix k for $1 \leq k \leq K$. Let $\lambda_k \neq 0$, since the results are trivial otherwise. Recall that $\delta = 0$ if $|\lambda| = 1$ and $\delta = 1$ otherwise. Let $n \geq D_k$. Then

$$J_k^n = (\lambda_k I + W)^n = \sum_{m=0}^{D_k - 1} \lambda_k^{n-m} C(n, m) W^m,$$

$$(18) \qquad J_k^n = \lambda_k^n C(n, D - \delta) \sum_{m=0}^{D_k-1} \lambda_k^{-m} \frac{C(n, m)}{C(n, D - \delta)} W^m.$$

Proof of Lemma 1. Substituting (18) into (9) yields

$$Q_{n,k} = \left(\frac{\lambda_k}{\lambda}\right)^n \sum_{m=0}^{D_k-1} \lambda_k^{-m} \frac{C(n, m)}{C(n, D - \delta)} W^m.$$

Since

$$C(n, m)/C(n, D - \delta) = O(n^{m-D+\delta}) \leqslant O(n^{D_k-D}) \quad \text{for } 0 \leqslant m \leqslant D_k - 1,$$

then

$$\|Q_{n,k}\| \leqslant |\lambda_k/\lambda|^n O(n^{D_k-D}).$$

    1. If $|\lambda_k| < |\lambda|$, then $|\lambda_k/\lambda|^n O(n^{D_k-D}) = O(n^{-1})$. Thus $Q_{n,k} = O(n^{-1})$, as desired.

    2. If $D_k \leqslant D - 1$, then $O(n^{D_k-D}) \leqslant O(n^{-1})$ while $|\lambda_k/\lambda|^n \leqslant 1$. Thus $Q_{n,k} = O(n^{-1})$, as desired.

    3. If $D_k = D$ and $|\lambda_k| = |\lambda|$, then

$$\left(\frac{\lambda_k}{\lambda}\right)^n \sum_{m=0}^{D_k-2} \lambda_k^{-m} \frac{C(n, m)}{C(n, D - \delta)} W^m = O(n^{-1})$$

by the proof of part 2 above. Hence $Q_{n,k}$ is dominated by the term $m = D_k - 1$; that is,

$$Q_{n,k} = \left(\frac{\lambda_k}{\lambda}\right)^n \left\{ \lambda_k^{1-D} \frac{C(n, D - 1)}{C(n, D - \delta)} W^{D-1} \right\} + O(n^{-1}).$$

Since $\delta = 0$ or $\delta = 1$, then

$$C(n, D - 1)/C(n, D - \delta) = \delta + O(n^{-1}).$$

Therefore

$$Q_{n,k} = \delta (\lambda_k/\lambda)^n \lambda_k^{1-D} W^{D-1} + O(n^{-1}),$$

which completes the proof of Lemma 1. □

Proof of Lemma 2. Write

$$(19) \qquad \mathbf{t}_{n,k} = \sum_{i=D_k}^{n} J_k^i \mathbf{w}_{n-i,k}.$$

Recall (10) and apply $\|\mathbf{w}_n\| \leqslant w$. Hence

$$\|\mathbf{s}_{n,k} - \mathbf{t}_{n,k}\| \leqslant w \sum_{i=0}^{D_k-1} \|J_k\|^i = O(1).$$

Hence

$$\lim_{n \to \infty} \|\mathbf{s}_{n,k} - \mathbf{t}_{n,k}\|/(\lambda^n C(n, D - \delta)) = 0.$$

Thus, it suffices to consider $\mathbf{t}_{n,k}$ instead of $\mathbf{s}_{n,k}$. Denote

(20) $$\mathbf{q}_{n,k} = \mathbf{t}_{n,k}/(\lambda^n C(n, D - \delta)).$$

Substitute (18) with $n = i$ and (19) into (20). Interchange the order of summation to obtain

(21) $$\mathbf{q}_{n,k} = \sum_{m=0}^{D_k-1} W^m \left\{ \sum_{i=D_k}^{n} \lambda_k^{i-m}\lambda^{-n} \frac{C(i, m)}{C(n, D - \delta)} \mathbf{w}_{n-i,k} \right\}.$$

1. Suppose that $|\lambda_k| < |\lambda|$. Consider $\tau_k \geqslant 1$ such that $|\lambda_k| < |\tau_k| \leqslant |\lambda|$. ($\tau_k$ will be picked later.) Let $\mathbf{b}_{n,k}$ denote the vector

(22) $$\mathbf{b}_{n,k} = \sum_{m=0}^{D_k-1} \lambda_k^{-m} W^m \sum_{i=D_k}^{n} C(i, m)\left(\frac{\lambda_k}{\tau_k}\right)^i \tau_k^{i-n}\mathbf{w}_{n-i,k}.$$

Then Eq. (21) may be written as

(23) $$\mathbf{q}_{n,k} = \left(\frac{\tau_k}{\lambda}\right)^n \mathbf{b}_{n,k}/C(n, D - \delta).$$

Consider the functions $\psi_n(z) = \Sigma_{i=0}^{n} z^i$ and $\psi(z) = \Sigma_{i=0}^{\infty} z^i$. Since $\lim_{n\to\infty}\psi_n(z) \equiv \psi(z)$ is analytic for $|z| < 1$, then $\lim_{n\to\infty}\psi_n^{(m)}(z) \equiv \psi^{(m)}(z)$ is also analytic, and thus also absolutely convergent for $|z| < 1$ (superscript denotes differentiation). Thus

$$|\psi_n^{(m)}(z)| \leqslant \psi^{(m)}(|z|) \quad \text{for } |z| < 1.$$

It is not hard to verify that

(24) $$\sum_{i=m}^{n} C(i, m)z^i = \frac{1}{m!} z^m \psi_n^{(m)}(z).$$

Since $0 \leqslant m \leqslant D_k - 1$, $|\lambda_k/\tau_k| < 1$, $|\tau_k|^{i-n} \leqslant 1$ for $D_k \leqslant i \leqslant n$, and $\|\mathbf{w}_{n-i,k}\| \leqslant w$, then the norm of (22) yields

(25) $$\|\mathbf{b}_{n,k}\| \leqslant w \sum_{m=0}^{D_k-1} |\lambda_k|^{-m}\|W^m\| \frac{1}{m!} \psi^{(m)}(|\lambda_k|/|\tau_k|) \equiv b.$$

Clearly, $b = O(1)$. Take norms in (23) to obtain

$$\|\mathbf{q}_{n,k}\| \leqslant b \left|\frac{\tau_k}{\lambda}\right|^n \bigg/ C(n, D - \delta).$$

If $|\lambda| > 1$, choose $\tau_k < |\lambda|$; in this case $\mathbf{q}_{n,k} = O(n^{-1})$. If $|\lambda| = 1$, then $\delta = 0$; in this case $1/C(n, D - \delta) = O(n^{-1})$ and thus $\mathbf{q}_{n,k} = O(n^{-1})$. This establishes part 1 of Lemma 2.

2. Suppose that $1 \leqslant D_k \leqslant D - 1$. In view of part 1, it is only necessary to prove part 2 when $|\lambda_k| = |\lambda|$. Note that $0 \leqslant m \leqslant D_k - 1 \leqslant D - 2$. If $|\lambda| = 1$, then

$$\sum_{i=D_k}^{n} \frac{C(i, m)}{C(n, D - \delta)}|\lambda|^{i-n} \leqslant \sum_{i=m}^{n} \frac{C(i, m)}{C(n, D)} = \frac{C(n + 1, m + 1)}{C(n, D)}$$

$$\leqslant O(n^{m+1-D}) \leqslant O(n^{-1}).$$

If $|\lambda| > 1$, then

$$\sum_{i=D_k}^{n} \frac{C(i, m)}{C(n, D - \delta)} |\lambda|^{i-n} \leq \frac{C(n, D - 2)}{C(n, D - 1)} \cdot (1 + |\lambda|^{-1} + |\lambda|^{-2} + \cdots) \leq O(n^{-1}).$$

Thus, for $|\lambda| \geq 1$ and for $0 \leq m \leq D - 2$,

$$(26) \qquad \sum_{i=D_k}^{n} \frac{C(i, m)}{C(n, D - \delta)} |\lambda|^{i-n} = O(n^{-1}).$$

Take norms in (21), apply $|\lambda_k| = |\lambda|$, $\|w_{n-i,k}\| \leq w$, and (26) to obtain $\|q_{n,k}\| \leq O(n^{-1})$. This establishes part 2 of Lemma 2.

3. Suppose that $|\lambda_k| = |\lambda|$ and $D_k = D$. Then (21) becomes

$$q_{n,k} = \sum_{m=0}^{D-1} \lambda^{-n} \lambda_k^{n-m} W^m \sum_{i=D}^{n} \lambda_k^{i-n} \frac{C(i, m)}{C(n, D - \delta)} w_{n-i,k}$$

$$= \left(\frac{\lambda_k}{\lambda}\right)^n \sum_{m=0}^{D-1} \lambda_k^{-m} W^m \sum_{i=0}^{n-D} \lambda_k^{-i} \frac{C(n - i, m)}{C(n, D - \delta)} w_{i,k}.$$

We may write

$$(27) \qquad q_{n,k} = \left(\frac{\lambda_k}{\lambda}\right)^n \sum_{m=0}^{D-1} \lambda_k^{-m} W^m f_{k,m,n}(\lambda_k^{-1}),$$

where $f_{k,m,n}(z)$ is the vector polynomial

$$(28) \qquad f_{k,m,n}(z) = \sum_{i=0}^{n-D} z^i \frac{C(n - i, m)}{C(n, D - \delta)} w_{i,k}.$$

Hence

$$(29) \qquad \|f_{k,m,n}(z)\| \leq w \sum_{i=D}^{n} |z|^{n-i} \frac{C(i, m)}{C(n, D - \delta)}.$$

Let $z = \lambda_k^{-1}$. Since $|\lambda_k| = |\lambda| \geq 1$, we may apply (26) to (29) and obtain

$$\|f_{k,m,n}(\lambda_k^{-1})\| = O(n^{-1}) \quad \text{for } 0 \leq m \leq D - 2.$$

Thus $q_{n,k}$ in (27) is dominated by the term with $m = D - 1$. Evaluate (29) with $m = D - 1$ for $|z| \leq |\lambda^{-1}|$. If $|\lambda| > 1$, then $\delta = 1$ and

$$\|f_{k,D-1,n}(z)\| \leq w \frac{C(n, D - 1)}{C(n, D - 1)} \sum_{i=0}^{n} |\lambda|^{i-n}$$

$$\leq w(1 + |\lambda|^{-1} + |\lambda|^{-2} + \cdots) = \frac{w|\lambda|}{|\lambda| - 1}.$$

On the other hand if $|\lambda| = 1$, then $\delta = 0$ and

$$\|f_{k,D-1,n}(z)\| \leq w \left\{ \sum_{i=D-1}^{n} C(i, D - 1) - 1 \right\} \Big/ C(n, D)$$

$$= w\{C(n + 1, D) - 1\}/C(n, D) \leq w(n + 1)/(n + 1 - D) = O(1).$$

Thus $f_{k,D-1,n}(z)$ is bounded in norm uniformly in n for $|z| \leq |\lambda^{-1}|$. Hence

$$(30) \qquad f_k(z) \equiv \lim_{n \to \infty} f_{k,D-1,n}(z)$$

is analytic for $|z| \leqslant |\lambda^{-1}|$. (In fact $\mathbf{f}_k(z)$ is analytic for $|z| \leqslant 1$ when $|\lambda| = 1$ and for $|z| < 1$ when $|\lambda| > 1$.) Equation (27) may be written as

$$q_{n,k} = (\lambda_k/\lambda)^n \lambda_k^{1-D} W^{D-1} \mathbf{f}_k(\lambda_k^{-1}) + O(n^{-1}).$$

To complete the proof, take norms, recall that $|\lambda_k| = |\lambda|$, and take the limit as $n \to \infty$. $\square$
