(Received May 12, 1976)

IR absorption spectra of ten phenanthryl chalcones have been studied with a view to see the effect on stretching frequencies of  $\alpha,\beta$ -unsaturated carbonyl group when conjugated to the phenanthryl nucleus.

Infrared absorption spectra of chalcone analogues have been reported by several workers<sup>1, 2, 6, 10</sup>, but little attention has been paid to the effect of polynuclear groups on the stretching frequency of  $\alpha,\beta$ -unsaturated carbonyl group. The present work has, therefore, been undertaken to gain more information about the spectroscopic characteristics of phenanthryl chalcones, which may lead to interesting generalisations on the structure—spectra correlations.

The infrared absorption spectra of a simple open chain ketone, undisturbed by neighbouring groups, exhibits<sup>7</sup> absorption in the range 1720—1706 cm<sup>-1</sup>, acetophenone<sup>9</sup> gives strong peak for  $\nu_{\text{max}}$  C=O group at 1686 cm<sup>-1</sup>, isophorone (having olefinic conjugation with CO group) shows<sup>8</sup> stretching frequency for >CO group at 1672 cm<sup>-1</sup> and benzal-acetophenone has a strong band for  $\alpha,\beta$ -unsaturated keto group at 1667 cm<sup>-1</sup>. In present case of phenanthryl chalcones the frequencies for the said group fall in the range of 1655—1684 cm<sup>-1</sup>. Thus a gradual lowering in stretching frequency of ketonic group is observed. These findings clearly indicate that the conjugation of  $\alpha,\beta$ -unsaturated carbonyl group with phenanthryl nucleus results in lowering of stretching frequency. This behaviour may possibly be due to increase in length of olefinic conjugation on either side of the —CH=CH—CO-group and/or different canonical forms of the  $\text{C}=\text{O}$  group as illustrated below

\* Compound numbers correspond to those reported in Table 1.

ν = Stretching; δ = Bending (in-plane), ς = Bending (out of plane).

In addition to this an upward frequency shift is also observed as in case of compound nos. **2**, **3**, **5**, and **8**. This may be attributed to the presence of strong electronegative groups such as chloro, bromo, p-dimethylamino, etc. These functionals with their strong electron attracting power diminish the polar character of the carbonyl group link and consequently raise the stretching frequency.

### Experimental

The chalcones under study were derived<sup>3, 4</sup> from 2- and 3-acetyl phenanthrenes and benzaldehydes and were repeatedly crystallised from different organic solvents. The final purity was checked by thin layer chro-

matography on silica gel-G using petroleum ether (b.p. 40–60°) and ethyl acetate (5 : 1) as developer solvents<sup>5</sup> (Table 1).

Infrared absorption spectra were recorded in  $\text{CHCl}_3$  solution, 0.1 mm thickness, in the range 4000–650  $\text{cm}^{-1}$  on Beckman model IR-7 precision prism grating spectrophotometer. The region 825–750  $\text{cm}^{-1}$  has been obscured due to  $\text{CHCl}_3$  absorption and the assignment of various bands are reported in Table 2.
