Abstract: Phosphorylation of 2'-0-acetyl-3'-trifluoroacetamido-3'-deoxy-N²-palmitoylguanosine with N-morpholino-0,0-bis(1-benzotriazolyl)phosphate gives a 5'-phosphotriester. Removal of the benzotriazolyl group and addition of pyrophosphoric acid gave, after deblocking all protecting groups,  $\mbox{GTP}(3'\mbox{NH}_2)$ .

Riboguanosine 5'-triphosphate (GTP) binding proteins participate in a large number of biochemical processes, such as hormonal regulation of adenylate cyclase  $^{1}$ , interferon-induced antiviral response  $^{2}$ , assembly of tubulin into microtubules<sup>3</sup>, and binding and translocation of aminoacv]-tRNA to ribosomes 4. For further characterization of the GTP interactions on these proteins a number of GTP derivatives have been described, such as  $(^{35}S)$  guanosine-5'-0-(3-thiotriphosphate)<sup>1</sup> and the affinity labels 8-azido-guanosine 5'-triphosphate and 5'-p-fluorosulfonylbenzoyl quanosine<sup>6</sup>. For particular proteins, e.g. the peptide chain elongation factor EF-Tu, the stereospecific constraints on the nucleotide cofactor are rather high, and modification of the guanine moiety or at the 5' end causes a large drop in affinity<sup>4</sup>. The partially resolved 3-D structure of EF-Tu·GDP (cf. Fig. 1) indeed reveals hydrogen bond interactions with the base and the 5' phosphates, whereas the 2',3'-hydroxy groups are exposed to the solvent $^7$ . This led us to the idea of synthesizing  ${
m GTP}(3'{
m NH}_2)$  which should allow the introduction of any desired fluores-

cence or spin label at the 3' position. In the case of EF-Tu, the atom coordinates of the nucleotide at its binding site are well defined and could serve as a reference for the measurement of distant interactions

### FIG. 1

Three-dimensional model of EF-Tu with details of  $\alpha$ -helices (cylinders) and  $\beta$ -strands (arrows) in the nucleotide binding domain. Contact areas with the two tRNA molecules are supposed around residue nrs. 208 and 237. For further details see ref. 7, 9 and 10.

with other ligands such as tRNA with a similarly labelled 3'-amino-3'-deoxyadenosine at its 3' end $^8$ . In the light of the recent finding that EF-Tu can bind two tRNA molecules simultaneously $^{9,10}$ , such an approach would be especially useful.

The properly-protected 3'-amino-3'-deoxy-D-ribofuranose derivative  $\frac{1}{1}$  (see Scheme) plays a pivot role in our approach to the synthesis of GTP(3'NH<sub>2</sub>). Key intermediate  $\frac{1}{1}$  can be obtained by a multistep process starting either from D-glucose  $\frac{11}{12}$  or D-xylose  $\frac{13-15}{12}$ . On the other hand, Morr et al.  $\frac{16}{12}$  obtained intermediate  $\frac{1}{12}$  by acetolysis of 3'-amino-3'-deoxy-riboadenosine which could easily be isolated by fermentation from Helminthosporium sp. 125. In our approach, we adopted the recently developed method of Ozols et al.  $\frac{17}{12}$  for the preparation of  $\frac{1}{12}$ . According to this method, the 3-OH group of 1,2-isopropylidene-5-0-benzoyl- $\beta$ -D-xylofuranose was esterified with trifluoromethanesulfonic acid anhydride followed by substitution of the triflate function with lithium azide. Hydrogenolysis of the 3'-azido function with palladium on charcoal, and protection of the free amino group with trifluoroacetic anhydride  $\frac{18}{12}$ , afforded the fully-protected 3-amino-3-deoxy-ribose derivative  $\frac{1}{12}$ . Condensation of  $\frac{1}{12}$  with a persilylated  $\frac{12}{12}$ -acylguanine  $\frac{19}{12}$  derivative

Scheme 1

2 ( $R^1$ =trimethylsilyl;  $R^2$ =acyl) in 1,2-dichloroethane, and in the presence of the Friedel-Crafts catalyst trimethylsilyl trifluormethanesulfonate  $^{20,21}$ , would afford the fully-protected guanosine derivative  $\mathfrak{Z}.$  However, we found that condensation of  $\mathfrak{L}$  with guanine derivative 2, in which R<sup>2</sup>=acetyl or benzoyl, gave a moderate yield (experimental evidence not given here) of the required derivatives  $\frac{3}{2}$  (R<sup>2</sup>=acetyl or benzoyl). A higher yield of 3 (R<sup>2</sup>=palmitoyl) was obtained if we subjected the persilylated guanine derivative 2 carrying the lipophilic  $N^2$ -palmitoyl protecting group<sup>22</sup> to the condensation conditions mentioned above. Careful analysis of the crude reaction mixture by TLC indicated the presence of mainly the N-9 isomer (3) and presumably a small quantity of the N-7 isomer. The fully-protected derivative 3  $(R^2$ =palmitoyl) was now converted, by the following steps, into compound 4 having a free 5'-OH. Thus, short treatment of 3 with sodium methoxide, followed by selective protection of the 5'-OH with 4,4'-dimethoxytrityl chloride, afforded, after acetylation of the 2'-OH group with acetic anhydride and acid hydrolysis of the dimethoxytrityl group, compound 4 as a colourless glass.

The introduction of the triphosphate function was accomplished by applying the crystalline and easily accessible bifunctional phosphorylating agent  $5^{23}$ . Thus an excess of 5 in dioxane was added to compound 4 in the presence of N-methylimidazole. Work-up of the reaction mixture, after 2 h at  $20^{\circ}$ C, afforded the phosphotriester derivative 6 as a homogeneous solid in a good yield. Removal of the benzotriazolyl P-O protecting group from 6 to afford crude 7, was accomplished by treatment with triethylamine/water in acetonitrile. Crude 7 thus obtained was treated with the tri-butylammonium salt of pyrophosphoric acid in DMF for 16 h at  $20^{\circ}$ C. Ammonolysis of the reaction product afforded crude 8 which was purified by anion-exchange column chromatography. The homogeneity and identity of 8 was unambiguously ascertained by  $31^{\circ}$ P- and  $31^{\circ}$ H-NMR spectroscopy.

In conclusion, the data presented in this paper show that phosphorylation of the guanosine derivative  $\frac{4}{5}$  (R<sup>2</sup>=palmitoyl) with the bifunctional agent  $\frac{5}{5}$  presents a convenient route to the synthesis of GTP(3'-NH<sub>2</sub>). Preliminary competition experiments between ( $^3$ H)GTP and GTP(3'-NH<sub>2</sub>) for binding EF-TU revealed an only two-fold decreased affinity for the latter modified ribonucleotide.

### Experimental

General methods and materials: Dioxane, tetrahydrofuran, pyridine and acetonitrile were dried by heating with  $CaH_2$  under reflux for 16 h and then distilled. Dimethylformamide was stirred with  $CaH_2$  for 16 h and then distilled under reduced pressure. All solvents were stored over molecular sieves 4Å. 1,2-Dichloroethane was washed with concentrated sulfuric acid, water and 10% aqueous NaHCO $_3$  dried over CaCl $_2$  distilled from  $P_2 O_5$  and stored over molecular sieves  $4 \mbox{\ensuremath{\mbox{A}}}$  . Hexane, p-xylene and toluene were distilled and stored over sodium. Evaporations were carried out under reduced pressure (15 mm Hg) at 40 $^{
m O}$ C.  $^{
m l}$ H-NMR spectra were measured at 100 MHz using a Jeol JNPS 100 spectrometer or at 300 MHz with a Bruker WM 300 spectrometer, equipped with an Aspect 3000 computer, operating in the Fourier Transform mode.  $^{13}\mathrm{C-}$  and  $^{31}\mathrm{P-NMR}$ spectra were measured with a Jeol JNPS 100 spectrometer equipped with a EC-100 computer, operating in the Fourier Transform mode. Chemical shifts ( $\delta$ -values) are given in ppm relative to tetramethylsilane ( $^1$ H-NMR) or tetramethylammonium chloride ( $^{13}$ C-NMR), and 85%  $H_3$ PO<sub>4</sub> as an external reference for  $^{31}P$ -NMR spectroscopy. Compounds were visualized by UV-light, or by spraying wit the appropriate reagents. Thus compounds containing sugar moieties were visualized by spraying with sulfuric acid (20%; v/v) or molybdato phosphoric acid/acetic acid/sulfuric acid (25 g/500 ml/25 ml). Compounds containing aliphatic amino groups were detected by ninhydrine spray reagent (Merck). TLC was performed on Silicagel (DC-fertigfolien F 1500 LS 254, Schleicher & Schüll). Solvent system A: chloroform/methanol (92:8, v/v) unless otherwise stated. Column chromatography was performed on silicagel (Merck, Kieselgel, 230-400 mesh). High performance anion-exchange chromatography was performed with the strong anion-exchange resin Permaphase AAX (Dupont, USA) dry-packed into a stainless-steël column (1 m x 2.1 mm). Gradient elution was affected by building up a linear gradient starting with buffer A (0.005 M  $\mathrm{KH_2PO_4}$ , pH 4.5) and applying 1% of buffer B (0.1 M  $\mathrm{KH_2PO_4}$ , 1.0 M KCl, pH 4.5) per min. A flow of 1 ml/min at a pressure of 8 MP at 20 °C was standard.

9'-(2'-0-acetyl-3'-deoxy-3'-trifluoroacetamido-5'-0-benzoyl- $\beta$ -D-ribo-furanosyl)- $N^2$ -palmitoylguanosine (3)

 ${
m N}^2$ -Palmitoylguanine (5.5 g, 14.1 mmole) was, after coevaporation with

anhydrous pyridine (3 x 30 ml), refluxed for 7 h with hexamethyldisilazane (HMDS, 25 ml), trimethylchlorosilane (TCS, 0.5 ml) and anhydrous pyridine (5 ml). The excess HMDS and pyridine were removed by coevaporation twice with anhydrous p-xylene (25-50 ml). The solid yellow silyl compound 2 (1.63 g, 3.1 mmole) was dissolved together with compound 1 (1.13 g, 2.6 mmole) in 1,2-dichloroethane (20 ml) and coevaporated twice with anhydrous toluene (2 x 50 ml) to afford an oil. The oil was redissolved in 1,2-dichloroethane (70 ml) and trimethylsilyltriflate (0.85 g, 3.85 mmole) was added. The mixture was gently refluxed in an atmosphere of dry nitrogen. After 6 h, TLC (system A) showed the reaction to be complete. Mainly two products in a ratio of 1:10 could be detected by TLC (A) analysis. The reaction mixture was diluted with chloroform (100 ml) and washed with aqueous sodium hydrogen carbonate (10%, v/v, 25 ml) and water (25 ml). The organic layer was dried  $(MgSO_A)$  and evaporated to afford a light brown oil. The crude product was dissolved in chloroform and purified on a column (8  $\times$  12  $\text{cm}^2$ ) of Kieselgel (230-400 mesh). Elution of the column with chloroform/methanol (100:0  $\rightarrow$  98:2, v/v) afforded 3 as a yellow glass. Yield 1.46 g (73%). Rf(A): 0.36.

9-(2'-0-acetyl-3'-deoxy-3'-trifluoroacetamido- $\beta$ -D-ribofuranosyl)- $N^2$ -palmitoylguanosine (4)

Compound 3 (0.7 g, 0.92 mmole) was dissolved in anhydrous methanol/py-

ridine (8.8 ml, 1/1, v/v) and treated with sodium methoxide (1 M, 2.8 ms)ml). After 10 min, TLC analysis showed the reaction to be complete (System A,  $0.36 \rightarrow 0.15$ ), and the reaction mixture was guenced by the addition of a slight excess of pyridine-HCl salt. The reaction mixture was coevaporated three times with anhydrous pyridine and the precipitated NaCl salts were filtered off over a bed of celite Hyflo supercel. The filtrate was concentrated under reduced pressure to give a yellow oil. To the magnetically stirred solution of the oil (0.5 g  $\sim$  0.81 mmole) in anhydrous pyridine (4 ml) was added dimethoxytrityl chloride (0.34 g, 1.00 mmole). TLC analysis (System A), after 3 h, showed a more lypophilic product  $[Rf(A): 0.15 \rightarrow 0.48]$  and that no starting material was left. Acetic anhydride (0.7 ml, 7.9 mmole) was now added to the reaction mixture. After 16 h at 0-5°C, TLC analysis (System A) showed the reaction to be complete. Water was added (10 ml) and the mixture was concentrated under reduced pressure and coevaporated with toluene  $(2 \times 25 \text{ ml})$ , dry ethanol  $(2 \times 25 \text{ ml})$  and chloroform  $(2 \times 25 \text{ ml})$ . Short column purification afforded the fully protected compound as a yellow glass. Yield 0.65 g (84%). Rf(A): 0.60. The fully protected compound 4 (0.65 q, 0.68 mmole) was dissolved in 15.4 ml dichloromethane/methanol (3:7, v/v). To the magnetically stirred solution was added 15.4 ml of a stock solution containing 4% benzenesulfonic acid in chloroform/methanol (7:3, v/v). TLC analysis (System A), after 5 min, showed complete removal of the dimethoxytrityl group [Rf(A):  $0.60 \rightarrow 0.25$ ]. The reaction mixture was diluted with chloroform (100 ml) and washed with sodium hydrogen carbonate (10%, v/v, 25 ml) and water (25 ml). The organic layer was dried  $(MgSO_1)$ , concentrated to an oil and triturated with petroleumether  $(40-60^{\circ}\text{C}, 2 \times 100 \text{ ml})$ . The precipitate was redissolved in chloroform and chromatographed on a Kieselgel column (230-400 mesh). Elution of the column with chloroform/methanol (94:6, v/v) and evaporation of the appropriate fractions afforded pure 4 as a white glass. Yield 0.43 g (71% based on 3). Rf(A): 0.25.

<sup>1</sup>H-NMR (300 MHz) (CDCl<sub>3</sub>): δ = 0.75 (t, 3xH, 0=C-(CH<sub>2</sub>)<sub>14</sub>-CH<sub>3</sub>); 1.30 (m, 26H, 0=C-CH<sub>2</sub>(CH<sub>2</sub>)<sub>13</sub>CH<sub>3</sub>); 1.70 (t, 3xH, acetyl); 2.52 (t, 2xH, 0=C-CH<sub>2</sub>-(CH<sub>2</sub>)<sub>13</sub>-CH<sub>3</sub>); 3.77 (m, 2xH, H<sub>5</sub>', H<sub>5</sub>"); 4.28 (m, 1xH, H<sub>4</sub>'); 5.05 (t, 1xH, H<sub>3</sub>'); 5.72 (m, 1xH, H<sub>2</sub>'); 6.0 (d, 1xH, H<sub>1</sub>', J<sub>1'-2'</sub> = 4 Hz). Anal. calc. for  $C_{30}H_{45}N_{6}O_{7}F_{3}$  (658.72): C, 54.70; H, 6.89; N, 12.76. Found: C, 54.00; H, 6.33; N, 12.90.

9-[2'-0-acetyl-3'-deoxy-3'-trifluoroacetamido-5'-0-phosphoryl-morpholi-no-(1-benzotriazolyl)-phosphate- $\beta$ -D-ribofuranosyl]-N<sup>2</sup>-palmitoyl-guanosine (6)

N-Morpholino-0,0-bis(1-benzotriazolyl)phosphate 5 (5.2 ml of a 0.2 M stock solution in anhydrous dioxane) and 1-methylimidazole (0.42 ml, 4.73 mmole) in anhydrous dioxane (5.2 ml) were added to compound 4 (0.28 g, 0.43 mmole). After stirring for 120 min at  $20^{\circ}$ C, TLC analysis (System A) showed the reaction to be complete. The reaction mixture was diluted with chloroform (30 ml) and extracted three times with cold triethylammonium bicarbonate (0.9 M, 3 x 6 ml), water (2 x 6 ml), KH<sub>2</sub>PO<sub>4</sub>-solution (0.15 M, 2 x 6 ml, pH 6) and water (1 x 6 ml). The organic layer was dried with petroleum-ether (40-60°C, 100 ml). The precipitate was filtered off and dried in vacuo (P<sub>2</sub>O<sub>5</sub>). Yield of 6, which was isolated as a white precipitate, was 0.32 g (81%). Rf(A): 0.42.  $^{31}$ P{ $^{1}$ H}-NMR (CDCl $_{3}$ ):  $\delta$  9.36, 8.61 (s, diastereoisomers).

# Synthesis of 3'-deoxy-3'-amino-riboguanosine-5'-triphosphate (8)

Compound 6 (0.30 g, 0.32 mmole) was dissolved in acetonitrile (4 ml) and triethylamine (2 ml) and water (1 ml) was added. TLC analysis (System A), after 4 h, showed complete conversion of the starting product into base-line material. To the crude product 7 thus obtained was added dioxane (10 ml) and the mixture was concentrated carefully to a small volume which was evaporated with dry toluene (3 x 15 ml). Anhydrous DMF (4 ml) and the tri-n-butylammonium salt of pyrophosphoric acid in DMF (4 ml, 0.5 M) were added to compound 7, and the solution was kept under the exclusion of moisture at room temperature for a period of 16 h. The mixture was concentrated to a small volume (4 ml) and aqueous ammonia (27 ml, 25%, v/v) was added. After 50 h at room temperature, the mixture was concentrated to a small volume. The resulting mixture was diluted with aqueous HCl (pH 3) (10 ml) and washed with ether (2 x 30 ml). The clear aqueous solution was basified to pH 8 by the addition of triethylamine. The crude product thus obtained was applied on a column (26 x 6 cm $^2$ ) of DEAE-Sephadex A25 ( $HCO_3^-$ -form), suspended in 0.05 M triethylammonium bicarbonate (TEAB). The column was eluted with a linear gradient starting from 0.05 M  $\rightarrow$  1.0 M TEAB in 40 h. The flow rate was 30 ml per h. Fractions of 6 ml were collected and

analysed by anion-exchange HPLC-analysis. Fractions containing the pure product were collected and evaporated under diminished pressure to a small volume and lyophilized. Compound 8 was brought into the sodiumform by passing it through a column (15 x 2 cm²) of Dowex 50W cation-exchange resin (100-200 mesh, sodium-form). The resulting aqueous solution was relyophilized. Yield of 8, which was isolated as a white powder, was 0.100 g (44%).

 $^{1}$ H-NMR (300 MHz) (D<sub>2</sub>0): 4.28 (t, 2xH, H<sub>5</sub>'H<sub>5</sub>"); 4.50 (q, 1xH, H<sub>4</sub>'); 4.67 (m, 1xH, H<sub>3</sub>'); 4.88 (q, 1xH, H<sub>2</sub>', J<sub>1'-2'</sub> = 3 Hz, J<sub>2'-3'</sub> = 7 Hz); 6.0 (d, 1xH, H<sub>1</sub>'); 8.02 (s, 1xH, H<sub>8</sub>, exo-cyclic base).

Tetramethylammonium chloride (TMA) was used as an internal reference,  $\delta$ -values are given relative to tetramethylsilane (TMS) ( $\delta$ TMA -  $\delta$ TMS = 3.18 ppm).

 $^{31}P\{^{1}H\}$ -NMR ( $D_{2}O$ ): At pH 7.3:  $\alpha P = -11.20$  (d, J = 19.5 Hz);  $\beta P = -22.3$  (dd, J = 19.5 Hz, J = 19.0 Hz);  $\gamma P = -9.2$  (d, J = 19.5 Hz).
