A zinc or indium-mediated Barbier-type addition reaction of 2,3-allenals with allyl bromide in a mixed medium of aqueous  $NH_4Cl$  and THF (5 : 2) was developed to provide an efficient route to 1,5,6-alkatrien-4-ols, which is synthetically very useful. No 1,4-addition reaction was observed. Depending on the substrates, both indium and activated zinc afforded the 1,2-addition products in moderate to excellent yields: for terminal allenals, activated zinc was better while in other cases the yields with indium were relatively higher.

# Introduction

Recently, much attention has been paid to the transition metalcatalyzed or mediated reaction of functionalized allenes.<sup>1,2</sup> In the case of 2,3-allenols, we and others have developed some methodologies for the synthesis of 2,5-dihydrofurans,<sup>3</sup>  $\alpha$ -methylene lactones,<sup>4</sup> vinylic epoxides,<sup>5</sup> and  $\alpha$ - or  $\beta$ -amino alcohols<sup>6</sup> starting from 2,3-allenols. A number of methods have been reported for the synthesis of 2,3-allenols: (1) the reactions of the mono-O-tetrahydropyran-2-yl derivatives of butyn-1,4-diols,7 allenic ketones,8 4-chlorobut-2-yn-1-ol,9 or 2,3-allenoates10 with LiAlH4 or DIBAL-H; (2) the Sn(II)-,<sup>11</sup> Cr(II)-<sup>11</sup> or In-<sup>12</sup> mediated reaction of propargylic bromides with aldehydes or ketones; (3) the reaction of 1,2-allenyl lithium with aldehydes<sup>13</sup> or ketones;<sup>13</sup> (4) the Cu(1)mediated homologation of terminal propargylic alcohols.<sup>14</sup> On the other hand, the Barbier-type reaction between allyl halide and carbonyl compounds to afford homoallylic alcohols in aqueous media has become a very useful synthetic transformation. The metals that have been used in the aqueous Barbiertype reactions include aluminium,15 magnesium,16 manganese,17 zinc,<sup>18</sup> antimony,<sup>19</sup> gallium,<sup>20</sup> indium,<sup>21</sup> bismuth,<sup>22</sup> tin,<sup>23</sup> lead,<sup>24</sup> and cadmium,25 etc. Of these metals, zinc offers the greatest potential for industrial application because of its relative low cost and ready availability. Indium<sup>26</sup> has the lowest first ionization potential relative to zinc, tin and magnesium. Therefore, it is facile to effect SET (single electron transfer) processes. In addition, it is not sensitive to boiling water or alkali and does not form oxides readily in air, which makes indium a promising metal for aqueous Barbier-type reactions. Herein, we wish to report our recent studies on Barbier-type allylations of 2,3-allenals with allyl bromide using indium and activated zinc in water.

#### Synthesis of Starting Materials

4-Mono-substituted or 4,4-disubstituted 2,3-allenals were prepared from the reaction of 1,2-allenyl lithium with DMF by a modified procedure developed by us (Table 1).<sup>13b</sup>

2-Substituted 2,3-allenals are easily available from 2,3-allenols by Swern oxidation (Table 2).<sup>27</sup>

As a starting point, the Barbier-type addition reaction of 4,4pentamethylenebutadienal 1a was chosen to establish the protocol. Some representative results are listed in Table 3. From Table 3, it was observed that with 2 equiv. of indium the reaction of 2 equiv. of allyl bromide with 1a in a mixed solvent of THF and water (2:5) at room temperature afforded 1,1-pentamethylene-1,2,6-heptatrien-4-ol 2a in 59% yield (entry 1, Table 3). By using saturated aqueous NH<sub>4</sub>Cl solution instead of water, the yield of the product was improved greatly to 95% (compare entry 6 with entries 1-3, Table 3). With a lesser or greater amount of saturated aqueous NH<sub>4</sub>Cl solution, the yield dropped (entries 7 and 8, Table 3). We also observed that 2 equiv. of indium are necessary (compare entry 6 with entries 4 and 5, Table 3). Thus, conditions A (2 equiv. of allyl bromide, 2 equiv. of metal,  $NH_4Cl$  (sat. aq.) : THF = 5 : 2, rt) were established as the optimized reaction conditions. When indium was replaced with zinc powder, the reaction afforded 2a in 37% (entry 9, Table 3). The isolated yield was improved to

Subsequently, the scope of the allylation of different 2,3-allenals was studied with some typical results summarized in Table 4. Various differently substituted 2,3-allenals were successfully used to afford 1,5,6-alkatrien-4-ols in moderate to good yields. 4,4-Disubstituted (entries 1-4, Table 4), 2,4-disubstituted (entries 5 and 6, Table 4), 4-mono-substituted (entries 7-12, Table 4), 2mono-substituted (entries 13-18, Table 4), and fully substituted 2,3-allenals (entries 19 and 20, Table 4) all afforded the expected products smoothly, indicating the wide scope of this reaction. In most cases, the yields of 2,3-allenols with indium were higher than those with activated zinc (entries 1-12 and 19-20, Table 4), however, the reaction of terminal allenals with allyl bromide and activated zinc afforded the corresponding products in higher yields (entries 13-18, Table 4). In addition, it should be noted that in all the cases, 1,4-addition reaction to the conjugated C=C bond in the allenals was not observed, indicating the excellent chemoselectivity.

## Conclusions

In conclusion, we have developed a convenient aqueous allylation reaction of 2,3-allenals with allyl bromide by using zinc or indium

in a mixed solvent of saturated aqueous  $NH_4Cl$  solution and THF, providing an efficient route to 1,5,6-alkatrien-4-ols. Due to the synthetic potential of the products, easy availability of the starting materials, and mild reaction conditions, this method may be useful in organic synthesis. Further studies on the scope and synthetic applications of this reaction are being carried out in our laboratory.

# (1) Synthesis of 4,4-pentamethylenebutadienal (1a). Typical procedure

To a solution of vinylidenecyclohexane (3.21 g, 29.7 mmol) and THF (30 mL) was slowly added dropwise n-butyl lithium (11.1 mL, 2.5 M in hexane, 27.75 mmol) at -60 °C with stirring under a nitrogen atmosphere. After being stirred for 1.2 h at -55 °C, the mixture was cooled to -70 °C and a solution of anhydrous dimethylformamide (3.5 mL, d = 0.947, 3.31 g, 45.0 mmol) in anhydrous THF (10 mL) was added dropwise at this temperature. After being stirred at -70 °C for an additional 2.0 h, the mixture was poured into 500 mL of HCl (0.1 M, 0 °C) with vigorous stirring. The mixture was extracted with diethyl ether (50 mL  $\times$ 3) after returning to room temperature. The combined organic extract was washed with ice-water (40 mL  $\times$  3) and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>.
