ABSTRACT

Transition metal-catalyzed arylation and alkenylation of the α -bromoalkenyl phosphonates were investigated with organoboranes and -borates. Arylation was successful with the aryl boronic acids and a palladium catalyst, while alkenylation was found to proceed with alkenyl borates and a nickel catalyst. In addition, an intramolecular Diels–Alder reaction of the diene prepared by the alkenylation afforded the corresponding adduct.

Organo phosphonates have been used as substitutes of the corresponding esters and acids of high biological activity¹ and as convenient probes for designing antibodies on the basis of transition state models.² These investigations have been supported by organic synthesis; therefore, development of protocols for obtaining phosphonates of complex structures is inevitably important. However, investigation has been concentrated rather on phosphorylation of organic compounds such as alkynes, alkenes, and aldehydes, and hence C–C bond formation on simple phosphonates seems left behind. For example, alkenyl phosphonates with defined stereochemistry have been prepared by several methods³ such as palladium-catalyzed coupling reaction of alkenyl halides and hydrogen phosphonates (HP(O)(OR)₂),⁴ rhodium-cata-

lyzed addition of hydrogen phosphonates to acetylenes,⁵ and a Wittig-type reaction with methylenebisphosphonates,⁶ etc.,⁷ whereas 1,4-addition⁸ and other reactions⁹ of alkenyl phosphonates are reactions that have been reported so far. Herein,

we report arylation and alkenylation of alkenyl phosphonates by a method summarized in Scheme 1. Products **C** would

Scheme 1. Carbon–Carbon Bond Formation at the α -Position of Alkenyl Phosphonates

be precursors of the phosphonic acid version of α -aryl alkanolic acids,¹⁰ while dienes **D** are advanced intermediates for further transformation.

The key reaction is a transition metal-catalyzed coupling reaction of α -bromo compounds **B**, derived from alkenyl phosphonates **A**, with organometallics. Since information about the influence of the phosphonate group on the coupling reaction is limited to the reverse combination (α -phosphoalkenyl boranes and stannanes with halides),^{7c,9b} several coupling reagents such as organoboranes, -borates, and -zincs were chosen for the investigation. Aryl coupling proceeded efficiently with the aryl boronic acids. On the other hand, alkenylation was successful only with organoborates, which were developed by us recently. In addition, an intramolecular Diels–Alder reaction of compound **D** was studied.

Alkenyl phosphonates **1a–c** and **2a–c** with Me, C₅H₁₁, and Ph groups were selected as compounds **A** of Scheme 1 and prepared in good yields without contamination of the stereoisomers by the Hirao method⁴ with modification.¹¹ As summarized in Scheme 2, bromination of these alkenyl

phosphonates at 10 °C–rt followed by reaction of the crude bromine adducts with Et₃N at 40 °C in CH₂Cl₂ afforded bromides **3a–c** from **1a–c** and **4a–c** from **2a–c** in good yields (Table 1). Although anti addition of Br₂ followed by

anti elimination of HBr was the major stereochemical course, stereoselectivity was varied from quite high (entries 1 and 3) to moderate (entries 5 and 6) depending on the substituent R¹ and the stereochemistry of the substrates.¹² Fortunately, large differences in R_f values¹³ of the products allowed easy purification of the major products by routine chromatography on silica gel.

Arylation of the α -bromoalkenyl phosphonates **3a–c** and **4a–c** was investigated with aryl boronic acids, which are well-established reagents of high reactivity.¹⁴ The results are presented in Table 2.¹² Coupling was investigated first with (*Z*)-isomer **3a** (R¹ = Me), a sterically more congested isomer than the corresponding (*E*)-isomer **4a** due to the projection of R¹ (= Me) toward the reaction site. The phenylation of **3a** and PhB(OH)₂ proceeded successfully under the conditions reported¹⁵ with Pd(PPh₃)₄ (5 mol %) and Na₂CO₃ (1 equiv) at 90–95 °C for 5 h in DME to furnish product **5a** in 93% yield (entry 1). No isomer of **5a** (i.e., **6a**) was detected by TLC analysis and ¹H NMR spectroscopy. Substrates **3b** and **3c** with the more bulky C₅H₁₁ and Ph substituents as R¹ also produced the phenylation products **5e** and **5f**, respectively, in good yields with retention of the stereochemistry (entries 5 and 6). As for boronic acids, *p*-Me-C₆H₄-B(OH)₂ and *p*-MeO-C₆H₄-B(OH)₂ showed reactivity similar to that of PhB(OH)₂ in the reaction with **3a** to provide **5b** and **5c** in good yields (entries 2 and 3). Likewise, *p*-(CH₂=CH)-

^a Isolated yield.

C₆H₄-B(OH)₂ produced **5d** in 81% yield (entry 4), which is a new monomer in polymer science.

Next examined was phenylation of (*E*)-isomers **4a–c**, which under the same reaction conditions used for the (*Z*)-isomers proceeded smoothly to furnish **6a–c** in high yields (entries 7–9).

Recently, synthesis of α -aryl compounds of type **6** has been reported by Srebniak.^{7d} This method is, however, restricted to production of (*Z*)-isomers **6** and suffers from moderate to low yields of 72–20%. On the contrary, the present method covers production of both isomers in high yields.

In contrast to the above arylation, alkenylation of **3a** with heptenylboronic acid (**7**) (Figure 1), which was selected as

**Figure 1.** Alkenyl reagents **7–9** we examined for coupling with **3** and **4**; coupling products **10** and **11** were obtained from **9**.

a representative alkenyl boronic acid, did not proceed under the arylation conditions described above and resulted in recovery of **3a**. Use of zinc reagent **8** and Pd(PPh₃)₄ as a catalyst at rt–50 °C in THF was also unsuccessful, producing a complex mixture.

These results recall the less reactive nature of α -iodo enones to the coupling reaction.¹⁶ After several fruitless reactions, borate **9**¹⁷ with a nickel catalyst, a reagent system developed by us for coupling with sterically congested *cis* alkenyl bromides,¹⁸ was found to furnish the coupling product **10a** (R¹ = Me). Although <20% was recorded under the original reaction conditions (NiCl₂(dppf), rt, THF), a slightly higher temperature of 40 °C raised the yield to 59% (Table 3, entry 1), though accompanied with stereoisomer **11a** (R¹

Table 3. Coupling Reaction of **3a,b** and **4a,b** with Alkenyl Reagent **9** and a Nickel Catalyst^a

entry	R ¹	substrate	conditions ^b	products ^c and yields (%) ^d

^a NiCl₂(dppf) (5–10 mol %). ^b THF was used as a solvent. ^c Separated easily by routine chromatography on silica gel. ^d Isolated yields.

= Me) in 17% yield. Fortunately, **10a** and **11a** were easily separated by routine chromatography on silica gel because of the large difference in *R_f* values between **10a** and **11a** ($\Delta R_f = 0.17$ with 2:3 hexane/EtOAc). Similarly, **3b** afforded **10b** (R¹ = C₅H₁₁) and **11b** in 57 and 19% yields, respectively, with ΔR_f of 0.17 (entry 2). Reaction of less congested (*Z*)-isomers **4a** and **4b** proceeded at room temperature to afford **11a** (R¹ = Me) and **11b** (R¹ = C₅H₁₁) as the major products (entries 3 and 4).¹⁹

The above protocol with a borate/Ni catalyst was extended to the sterically more congested borate **12**,¹⁷ which furnished product **13**¹² in 59% yield with the isomer in 19% yield ($\Delta R_f = 0.15$) (eq 1).

Recently, dienes of type **11** have been synthesized through zirconacycles.^{7a} However, the present method is more flexible in providing other stereoisomers such as **10** and **13**, the latter of which is the most congested diene.

Scheme 3. Diels–Alder Reaction of Diene **18**

^a Stereochemistry shown in the structure is that tentatively assigned.

The multifunctional groups of the products are attractive for further transformation to more complex compounds. Asymmetric hydroxylation, asymmetric hydrogenation, Diels–Alder reaction, and 1,4-addition are such reactions. Thus,

we investigated briefly the intramolecular Diels–Alder reaction of **17**, which was prepared by coupling reaction between bromide **4a** and borate **15**¹⁷ followed by deprotection of the TBS group and subsequent vinylation (Scheme 3). Diels–Alder reaction of **17** proceeded successfully at 160–170 °C in toluene for 15 h to produce adduct **18** in 55% yield.

In conclusion, we have shown arylation and alkenylation of α -bromoalkenyl phosphonates. The products are a new class of phosphonates with unique structures and functionalities and will be useful in fields such as pharmacology and polymer science.²⁰

Supporting Information Available: Typical experimental procedures, spectral data for all new compounds, and a list of alkenyl phosphonates with coupling constants used for determination of the olefin geometries. This material is available free of charge via the Internet at <http://pubs.acs.org>.

OL020167S

(19) Alkenylation of boronides **3c** and **4c** with **9** proceeded as well. However, products from **3c** and **4c** were identical by ¹H NMR spectroscopy and TLC analysis. Unfortunately, the stereochemistry of the trisubstituted olefin of the product could not be determined because of overlap of the signals.

(20) All new compounds were characterized by IR and ¹H NMR spectra.
