## ABSTRACT

The methylenecyclopropanes (MCPs) react with various metal chlorides or bromides to give the corresponding homoallylic chlorides or bromides in good yields.

Methylenecyclopropanes (MCPs) are highly strained but readily accessible molecules that have served as useful building blocks in organic synthesis.<sup>1</sup> MCPs undergo a variety of ring-opening reactions because the relief of ring strain provides a potent thermodynamic driving force. Three kinds of reaction patterns of MCPs have been disclosed (Scheme 1) for reactions with transition metals such as Pd,

Rh, Ru, and Pt. MCPs can react with polar reactants such as ROH,<sup>2</sup> R<sub>2</sub>NH,<sup>3</sup> malonate derivatives,<sup>4</sup> carbon dioxide,<sup>5</sup> al-

dehydes,<sup>6</sup> and imines<sup>7</sup> in the presence of a Pd catalyst to give type I products. MCPs also can react with nonpolar reactants such as R<sub>3</sub>SiH,<sup>8</sup> R<sub>3</sub>SnH,<sup>9</sup> R<sub>2</sub>B-BR<sub>2</sub>,<sup>10</sup> R<sub>3</sub>Si-BR<sub>2</sub>,<sup>11</sup> R<sub>3</sub>Si-CN,<sup>12</sup> and olefins<sup>13</sup> in the presence of a Pd, Ru, Rh,

or Pt metal catalyst to afford the type II and/or type III products depending on the reaction conditions (Scheme 1).

Recently, we found that the ring-opening reactions of MCPs 1 with alcohols and other nucleophiles catalyzed by Lewis acids  $[Ln(OTf)_3]$  took place via another novel manner to give the corresponding ring-opened products under mild conditions.<sup>14</sup> This interesting result stimulated us to further investigate the Lewis acid-catalyzed reactions of MCPs 1 with other reactants. Herein we wish to report the ring-opening reactions of MCPs 1 promoted by metal halides (Lewis acids) under mild conditions in which homoallylic halides can be obtained in high yields in dichloromethane (DCM) (Scheme 2).

During our own investigations, we found that MCPs 1 could react with many metal halides (Lewis acids) to give the corresponding ring-opened homoallylic halides in good yields, and the Lewis acidities of metal halides played a critical role in this reaction. Using diphenylmethylenecyclopropane 1a (0.5 mmol) as the substrate, various metal chlorides (0.75 mmol) have been tested for this ring-opening reaction in dichloromethane (DCM) at room temperature (20 °C). The results were summarized in Table 1. The reactions proceeded smoothly in the presence of TiCl<sub>4</sub>, BiCl<sub>3</sub>, FeCl<sub>3</sub>, or AlCl<sub>3</sub> (strong Lewis acids) to give the corresponding homoallylic chloride 2a in good yields (Table 1, entries 1–4),

but using  $ZnCl_2$  or  $CoCl_2$  (weak Lewis acid) as the catalyst, no reaction occurred (Table 1, entries 6 and 7). In addition, only a trace of **2a** was formed in the presence of  $CuCl_2$  (Table 1, entry 5).

Next, we utilized  $TiCl_4$  and  $BiCl_3$  as the Lewis acid promoters to examine the ring-opening reactions of various MCPs **1**. The results were shown in Table 2. For MCPs

<sup>*a*</sup> All reactions were carried out with MCPs (1a-h) (0.5 mmol) and metal chloride (0.75 mmol) using DCM solvent at room temperature and then quenched with water. <sup>*b*</sup> All yields were isolated yields.

**1a**-d (both R<sup>1</sup> and R<sup>2</sup> are aromatic groups), the reactions proceeded very well to give **2a**-g in high yields within 2 h in the presence of TiCl<sub>4</sub> (Table 2, entries 1–4). For MCPs **1e,f** (both R<sup>1</sup> and R<sup>2</sup> are aliphatic groups), the corresponding homoallylic chlorides **2e** and **2f** were obtained in higher yields using BiCl<sub>3</sub> as the Lewis acid catalyst (reagent) for 24 h (Table 2, entries 5–8). However, it should be noted that for **1g,h** (R<sup>1</sup> is aromatic group and R<sup>2</sup> is hydrogen atom) and **1i** (R<sup>1</sup> is aromatic group and R<sup>2</sup> is methyl group) the reactions only gave a trace of products in the presence of TiCl<sub>4</sub> or BiCl<sub>3</sub> (Table 2, entries 9–12). It seems to us that this kind of MCP **1g**-**i** polymerizes easily in the presence of metal halides (Lewis acids).

<sup>*a*</sup> All reactions were carried out with MCPs 1 (0.5 mmol) and titanium bromide (0.75 mol) using the DCM as solvents at room temperature and then quenched with water. <sup>*b*</sup> All yields were isolated yields.

aromatic groups), the reaction proceeds very well to give  $3\mathbf{a}-\mathbf{c}$  in high yields within 2 h (Table 3, entries 1–3). For aliphatic MCP **1f**, the corresponding homoallylic bromide **3f** was obtained in the presence of TiBr<sub>4</sub> in good yield for 24 h as well (Table 3, entry 4).

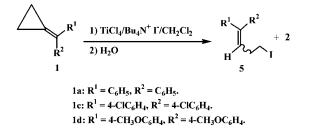

To complete this version of halogenation of MCPs **1**, we attempted to prepare the corresponding homoallylic iodides. We first conducted the reaction of MCP **1a** with TiI<sub>4</sub> under the same conditions as those described before. But, we found that this reaction only gave diiodide product **4** in high yield (95%) (Scheme 3). In fact, diiodide **4** can be obtained in the

presence of iodine ( $I_2$ ) quantitatively in DCM (Scheme 3). Because we can find the deep color of  $I_2$  in the reaction mixture of MCPs with TiI<sub>4</sub>, it can be concluded that part of TiI<sub>4</sub> was decomposed to  $I_2$  during the reaction and MCP **1a** further react with  $I_2$  to give diiodide product **4**.

To synthesize the corresponding homoallylic iodides 5, the  $TiCl_4/n$ -Bu<sub>4</sub>N<sup>•+</sup>I<sup>-</sup> (molar ratio 1/1.2) system developed

by Oshima was employed.<sup>15</sup> The iodides **5** were indeed obtained in good yields, but along with small amounts of the corresponding homoallylic chlorides **3** (Table 4, entries 1-3). Moreover, the two halogenated products could not be separated by silica gel flash column chromatograph.

To avoid the contamination of the corresponding homoallylic chlorides, we examined a  $BF_3 \cdot Et_2O/n-Bu_4N^{\bullet+}I^-$  (molar ratio: 1/1.5) system. We found that by means of this reaction system, the homoallylic iodides **5** could be isolated in excellent yields. The results were elucidated in Table 5. Only

for MCP **1d**, the homoallyilc iodide **5d** was obtained in low yield (Table 5, entry 4). This is because the  $BF_3 \cdot Et_2O/n$ - $Bu_4N \cdot H^-$  system can cleave the MeO- group from aromatic

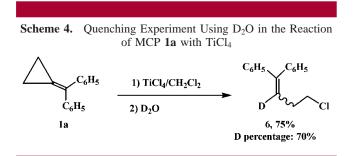

<sup>(15)</sup> Han, Z.; Uehira, S.; Shinokubo, H.; Oshima, K. J. Org. Chem. 2001, 66, 7854.

ring even at room temperature (the mono-demethyl product was isolated in 36% yield; see the Supporting Information).

In general, for unsymmetric MCPs 1 such as 1b, 1e, and 1f, the corresponding homoallylic halides are obtained as the E/Z mixture with low stereoselectivities.

With the success of the BF<sub>3</sub>•Et<sub>2</sub>O/*n*-Bu<sub>4</sub>N•<sup>+</sup>I<sup>-</sup> system, we then turned to the BF<sub>3</sub>•Et<sub>2</sub>O/*n*-Bu<sub>4</sub>N•<sup>+</sup>F<sup>-</sup> system in order to synthesize the corresponding homoallylic fluorides. But only a trace of homoallylic fluoride product was obtained under the same conditions. The major product was the homoallic alcohol derived from the reaction of MCPs with water in the presence of Lewis acid BF<sub>3</sub>•Et<sub>2</sub>O.<sup>14a</sup> This may be due to the weak nucleophilicity of fluoride ion and the large amount of water present in commercially available *n*-Bu<sub>4</sub>N•<sup>+</sup>F<sup>-</sup>.

To probe the mechanism of this reaction and clarify the proton source of this reaction, we quenched the reaction by D<sub>2</sub>O instead of H<sub>2</sub>O. As a result, the deuterated product **6** was isolated in 75% yield with 70% D (Scheme 4).<sup>16</sup> This result suggest that the hydrogen atoms of homoallylic halides were derived from the quenching proton source.

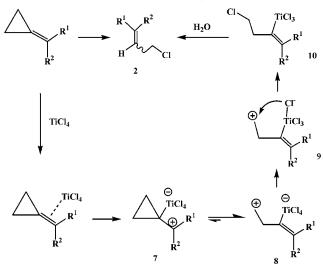

A plausible mechanism for the ring-opening reaction of MCPs 1 promoted by TiCl<sub>4</sub> was shown in Scheme 5. The rearrangement of carbon cation 7 to 8 induced by Lewis acid TiCl<sub>4</sub> was the key step of this reaction.<sup>17</sup> The intramolecular chlorination of 9 gave intermediate 10, which produced the final homoallylic chloride 2 by quenching with water.

After this work was submitted, Yamamoto reported that the reaction of alkylidenecyclopropanes with HCl or with

(17) Carey, F. A.; Tremper, H. S. J. Am. Chem. Soc. 1969, 91, 2967.

HBr proceeds very smoothly at 120 °C to produce the corresponding homoallylic halides stereoselectively in good to excellent yields.<sup>18</sup>

In conclusion, we disclosed a transformation process of MCPs **1** from the reaction with metal halides (Lewis acids) to give the corresponding homoallylic halides in high yields under mild reaction conditions. Efforts are in progress to elucidate the mechanistic details of this reaction and to determine its scope and limitations.
