## ABSTRACT

The bisphosphinite **4** incorporating two 7-phosphanorbornene subunits is an efficient ligand for the Rh-catalyzed enantioselective hydrogenation of functional alkenes in terms of rate and enantioselectivity. This type of structures is readily accessible by [4 + 2] cycloaddition of phospholes with dienophilic alkenes and can be easily fine-tuned.

During recent years, the Zhang group has developed the synthesis of the 7-phosphanorbornane structure and its applications in enantioselective catalysis.<sup>1</sup> From a synthetic standpoint, the related 7-phosphanorbornene structure is very readily accessible through the [4 + 2] cycloaddition of a phosphole dienic system with a dienophilic alkene. We have recently demonstrated that it is possible to enhance the dienic reactivity of phospholes with an appropriate choice of the P-substituents.<sup>2</sup> The 1-alkoxyphospholes appear to be especially reactive. Thus, we decided to perform a preliminary investigation of the potential of the readily available 7-alkoxy-7-phosphanorbornenes in asymmetric catalysis. Our first experiments were carried out with the monophosphinite **1** (enantiomeric purity 98%, (*S*)-configuration at phosphorus)<sup>2c</sup>

(Scheme 1). These experiments demonstrate that the rhodium complex of **1** is an efficient hydrogenation catalyst in terms of rate but not satisfactory in terms of enantioselectivity.

### Scheme 1. Asymmetric Hydrogenation of Functional Alkenes with Rh/Monophosphinite (**1**) Catalyst<sup>a</sup>

<sup>a</sup> Conditions: rt, MeOH, H<sub>2</sub> 3 atm, 1 % [RhL<sub>2</sub>(cod)]PF<sub>6</sub> as a catalyst.

Thus we decided to devise a simple synthesis of a chelating enantiopure bis(7-phosphanorbornene) structure. The starting 1-cyano-3,4-dimethylphosphole<sup>3</sup> was first converted into the

enantiopure bis(phosphole) **2** by reaction with the lithium derivative of (*R,R*)-1,2-diphenyl-1,2-ethanediol (99% ee)<sup>4</sup> and was stored as its borane complex **3**. It readily reacts with *N*-phenylmaleimide<sup>5</sup> to give the expected bis(7-phosphanorbornene) **4** as a single enantiomer (Scheme 2).

The stereochemistry of **4** was established by X-ray crystal structure analysis of its *cis*-PtCl<sub>2</sub> complex **5** (Figure 1). As

**Figure 1.** Crystal structure of complex **5**. Phenyls have been omitted for clarity.

can be seen, the alkoxy P-substituents are *anti* with respect to the phosphanorbornene C=C double bonds. The P–Pt–P bite angle is 88°. The two Pt–P bonds are slightly different at 2.183(3) and 2.222(3) Å, and the geometry of platinum is almost perfectly square-planar.

In the noncomplexed **4**, the two <sup>31</sup>P nuclei appear equivalent ( $\delta$  <sup>31</sup>P +100.2 in C<sub>6</sub>D<sub>6</sub>) whereas the frozen geometry of **5** induces a differentiation of the two nuclei ( $\delta$  <sup>31</sup>P +93.0 and +103.6 in CH<sub>2</sub>Cl<sub>2</sub>, <sup>2</sup>J<sub>P–P</sub> ca. 25 Hz, <sup>1</sup>J<sub>Pt–P</sub> 3800 and 3933 Hz).

The bisphosphinite **4** was tested on the same rhodium-catalyzed hydrogenation reactions of functional alkenes as the monophosphinite **1** (Scheme 3).

**Scheme 3.** Asymmetric Hydrogenation of Functional Alkenes with Rh/Bisphosphinite (**4**) Catalyst<sup>a</sup>

<sup>a</sup> Conditions: rt, H<sub>2</sub> 3 atm, 1 % [Rh(**4**)(cod)]PF<sub>6</sub> as a catalyst.

Although slightly less efficient than **1** in terms of rates, a drastic enhancement of the enantioselectivity is observed with **4**. These preliminary experiments illustrate the potential of the readily available 7-phosphanorbornenes in enantioselective catalysis. A fine-tuning of the structure can easily be achieved by a modification of the phosphole substitution scheme and the bridge connecting the two phosphorus atoms. Dienophiles other than *N*-phenylmaleimide can also be used. These various possibilities are currently under investigation.
