ABSTRACT

Relative energies in kcal/mol

	ΔE_1	ΔE_2	$E_2 - E_1$	$E_3 - E_1$
Best est.	1.9	19.8	14.3	25.0
B3LYP	-8.4	11.8	-0.2	1.9
M05-2X	1.4	16.8	16.9	25.4

It has recently been pointed out that current density functionals are inaccurate for computing stereoelectronic effects and energy differences of isomerization reactions and isodesmic reactions involving alkanes; this has been interpreted as an incorrect prediction of medium-range correlation energies. This letter shows that the recently published M05-2X functional has good accuracy for all three of the recently highlighted problems and should be useful for a wide variety of problems in organic chemistry.

Density functional theory (DFT) is now the main tool for calculating the structure and energetics of complex molecular systems and materials.¹ Recently, Grimme claimed that all state-of-the-art density functionals provide a qualitatively incorrect picture of the stereoelectronic effects in alkane isomers,² and these observations are reinforced by two independent works^{3,4} in this journal. Table 1 compares Grimme's results for four standard density functionals^{5–9} to

experimentally derived^{2,10} data for the zero-point exclusive energy of *n*-octane minus that of 2,2,3,3-tetramethylbutane. All four density functionals that he studied get the sign wrong. Grimme² pointed out that a related problem is the increasing size of the errors per bond in heats of formation and alkyl bond dissociation energies predicted by most density functionals when molecules get larger.^{3,11} We had

pointed out earlier that the new M05-2X density functional has much better performance than all previous density functionals for alkyl bond dissociation energies as a function of alkyl group size.¹² Unfortunately, Grimme did not test the M05-2X density functional for this problem. In fact, we report here that the M05-2X functional, with the 6-311+G(2df,2p) basis set,¹³ yields +2.1 kcal/mol (+1.4 kcal/mol with the cQZV3P¹⁴ basis set and MP2/TZV(d,p) geometries) for the quantity in Table 1, which is quantitatively correct.

Wodrich et al.³ showed that the systematic errors in DFT as the alkane size is increased are related to the stabilizing interaction of geminal methyl or methylene groups, an effect they call “protobranching,” which is sensitive to medium-range correlation energy. A good measure of this effect is provided by the energies of reaction for reactions such as

or

Table 2 compares these energies of reaction to experiment for several common density functionals and also M05-2X. Clearly, M05-2X is more accurate than previous functionals.

A related example, in particular, a case of DFT failing to account for stereoelectronic effects, was provided by Schrein-

simultaneous parametrization¹² of the M05-2X exchange and correlation functionals against a broad range of accurate data including noncovalent interactions for main group chemistry. This allowed us to better represent medium-range correlation energy. We note that the M05-2X functional involves kinetic energy density in both the exchange and correlation functionals, but unlike fifth-rung functionals,²⁵ it does not involve terms²⁶ dependent on virtual orbitals.

The calculations were carried out with a modified version of *Gaussian03*.²⁷ M05-2X is now available in release 5.0 of *NWChem*.²⁸ In addition it is scheduled to be in the next minor revision of *Gaussian03* and in the next release (version 7.0) of *Jaguar*.

The reader is referred to the original paper¹² and references therein for further details of the M05-2X functional. In one of our previous papers,²⁹ we analyzed the noncovalent interaction of methane with benzene and concluded that the success of M05-2X for this noncovalent interaction is due to its improved correlation functional for the description of medium-range correlation. We noted in ref 29 that although M05-2X does not give the asymptotic $-C_6/R^6$ tail of the long-range interaction, it agrees with CCSD(T)/complete-basis results for CH₄-benzene within 0.17 kcal/mol from 3.4 to 5.4 Å (the minimum is 1.5 kcal/mol at 3.8 Å and is 4.6 times deeper than the value at 5.4 Å).

We also note that the M05-2X functional has been shown to outperform many other functionals for noncovalent interactions,^{12,29,30} for torsional potentials of conjugated polyenes,³¹ and for proton affinities of conjugated polyenes (a test of its ability to predict polarizabilities of conjugated double bonds).³¹ It is less satisfactory for energy differences³² between cumulenes and poly-yenes, but still better than all other functionals in Tables 1–3.³¹ M05-2X also has very high quantitative accuracy for main-group thermochemistry and barrier heights.¹²
