## ABSTRACT

A novel distyryl-substituted boradiazaindacene (BODIPY) dye displays interesting properties as a sensitizer in DSSC systems, opening the way to further exploration of structure–efficiency correlation within this class of dyes.

Among environment friendly and renewable sources of energy, solar cells have always been high on the list of likely candidates. Unfortunately, large-scale commercialization is hampered by the production costs. Dye-sensitized solar cells<sup>1</sup> (DSSCs) appear to be highly promising alternatives to more expensive solar cell technologies. Considering the current

maximal level of overall conversion efficiency ( $\eta$ ) under simulated sunlight for DSSCs (11%),<sup>2</sup> improvements in efficiency and durability would certainly facilitate widespread utilization of this technology.

It is clear that there are a number of factors determining the efficiency of solar cells, but the structural and physical properties of the sensitizer are clearly important ones. As a result, many laboratories around the world have active

research programs in optimizing the dye component of the DSSCs. Ruthenium dyes, while holding the record for conversion efficiencies, have relatively low extinction coefficients, and they are also considered to be expensive and hard to purify. Motivated by the possibility of finding a replacement for metal-complex dyes, a number of chromophores, including coumarins,<sup>3</sup> indolines,<sup>4</sup> oligoenes,<sup>5</sup> merocyanines,<sup>6</sup> hemicyanines,<sup>7</sup> oligothiophenes,<sup>8</sup> functionalized thiophenes,<sup>9</sup> squaraines,<sup>10</sup> benzothiadiazoles,<sup>11</sup> perylene-tetracarboxylic acid derivatives,<sup>12</sup> diphenylaminostyrenes,<sup>13</sup> and phthalocyanines,<sup>14</sup> have been studied, with varying degrees of success. For the most efficient of these sensitizers, the overall conversion efficiency is limited to 4–7.5% (Figure 2).

Boradiazaindacenes (the parent dye, **1**), commonly known as BODIPY dyes, have been recognized<sup>15</sup> as useful fluorescent labels for biomolecules for some time. Within the past decade, there is much renewed interest<sup>16</sup> in these dyes, due to the development of new avenues for derivatization and novel applications in a highly diverse field, including chemosensors,<sup>17</sup> logic gates,<sup>18</sup> light harvesters,<sup>19</sup> energy transfer cassettes,<sup>20,21</sup> and photodynamic therapy.<sup>22</sup> It is known that photostability of the BODIPY dyes is signifi-

cantly better<sup>23</sup> than many sensitizers proposed. One simple derivative of BODIPY was in fact studied<sup>24</sup> as a sensitizer within the DSSC context, and charge separation was clearly observed; however, very low overall conversion efficiencies were obtained.

We now propose that, when judiciously designed, BODIPY dyes have certain unique features that could make them highly advantageous compared to most other organic dyes, and thus, they are highly promising in this regard. (i) BODIPY dyes have high extinction coefficients (70 000–80 000 M<sup>-1</sup> cm<sup>-1</sup>) and can easily be modified with any desired functionalities. (ii) Absorption peak can be moved to longer wavelengths through simple modifications, keeping strong absorption cross sections. (iii) BODIPY dyes have inherent asymmetry in charge redistribution when they undergo S<sub>0</sub>→S<sub>1</sub> transition upon excitation, increasing the charge density on the *meso*-carbon (C-8), while decreasing it in most other positions in the boradiazaindacene system (Supporting Information). This inherent directionality of charge redistribution pinpoints C-8 as the optimal position of charge injection. (iv) The directionality observed in excitation can be further enhanced with strategically placed electron-withdrawing and electron-donating groups, and on the basis of earlier work,<sup>25</sup> cyanoacrylic acid and 4-*N,N'*-diphenylaminophenyl groups are to be of tremendous utility in this regard.

With these considerations, we designed compound **2** (Figure 1). The synthesis is convenient; the BODIPY core

condensed with *N,N'*-diphenylaminobenzaldehyde (prepared from triphenylamine via Vilsmeier formylation). Following the deprotection of the aldehyde group, it was condensed with cyanoacetic acid to place electron-withdrawing cyano and the anchoring carboxylic acid groups in the desired positions. An important part of the design in this dye is to place the anchor and cyano group at the C-8 position, where the charge moves on excitation; a perfect placement for efficient charge injection.

DFT calculations for the dye **2**, at the B3PW91/6-31+G(d,p)//B3LYP/6-31G(d) level of the theory, support directional movement of charge on excitation (Supporting Information). The HOMO is primarily comprised of  $\pi$  framework of the BODIPY and the styryl groups, with significant contributions from  $\pi$  electrons of the diphenylamino substituent (Figure 3); whereas the LUMO is very

**Figure 3.** Schematic representation of the frontier orbitals (left, HOMO; right, LUMO) of compound **2** computed at the B3PW91/6-31+G(d,p)//B3LYP/6-31G(d) level of theory. The surfaces are generated with an isovalue at 0.02.

clearly confined to the  $\pi$  system of the anchor group. (See Supporting Information for the nearly identical orbital pictures obtained with other methods.) This overall picture, found at all levels considered, shows a very clear electron

density shift from the  $\pi$  framework of the BODIPY core and the styryl substituents to the pendant carboxyphenyl moiety upon a vertical excitation of the  $\pi$ - $\pi^*$  type.

Compound **2** has a relatively broad absorption peak at around 700 nm in chloroform solution, consistent with its charge transfer (ICT) characteristics (Figure 4). The molar

**Figure 4.** Overlaid absorption spectrum of the dye **2** in chloroform (red dashes) and the photocurrent action spectrum (black solid line) obtained under simulated sunlight (AM 1.5). Nearly constant photon-to-current conversion level between 400 and 800 nm is impressive but, at the same time, an indication of aggregation on the TiO<sub>2</sub> surface.

extinction coefficient at the peak wavelength was found to be 69 500 M<sup>-1</sup> cm<sup>-1</sup>. Two additional transitions at shorter wavelengths result in a panchromatic performance for this dye. Cyclic voltammetry of the compound **2** (Supporting Information) revealed a HOMO energy level of 5.088 eV and a LUMO energy level of 3.517 eV, which is at sufficiently high energy for thermodynamically favorable injection of electrons to nanocrystalline TiO<sub>2</sub>-CB. The dye-sensitized cell device was constructed in analogy to literature (for experimental details, see the Supporting Information). Characterization of the sandwich type cell (ESI) yielded short-circuit current (*J*<sub>sc</sub>) of 4.03 mA/cm<sup>2</sup>, open-circuit voltage (*V*<sub>oc</sub>) of 562 mV, and fill factor (FF) of 73.5%, giving an  $\eta$  of 1.66%. IPCE data (Figure 5) reveal a near constant photon-to-current conversion efficiency with a peak

**Figure 5.** Current versus voltage in the constructed cell. *V*<sub>oc</sub> = 562 mV, *J*<sub>sc</sub> = 4.03 mA/cm<sup>2</sup>, FF = 0.735,  $\eta$  = 1.66%. Cell's active surface area was 0.159 cm<sup>2</sup>, and the illumination intensity was 100 mW/cm<sup>2</sup> at 1.5 AM conditions.

value of 22% at 750 nm. This peak value, to the best of our knowledge, corresponds to the largest reported monochromatic incident photon-to-current conversion efficiency in the near IR region (i.e., at 750 nm) for organic dyes, and second to only a single tris(thiocyanato)terpyridyl–ruthenium complex dye.<sup>26</sup> In addition, we would like to point out that the reported  $\eta$  value was obtained without any of the additives typically used (e.g., cheno; 3a,4a-dihydroxy-5b-cholic acid) for enhancing conversion efficiencies.

In conclusion, we have demonstrated that boradiaza-indacenes or BODIPYs can be transformed into satisfactory sensitizers especially in the longer wavelength region of the visible and near-IR region of the solar spectrum. Further
