Dihydrobenzo[a]fluorene derivatives have been prepared by a formal intramolecular [3  $+$  3] cycloaddition of  $o$ -alkynylstyrenes bearing a secondary alkyl group at the  $\beta$ -position of the styrene moiety. The process, catalyzed by a cationic gold(I) complex, involves a 1,2-hydride migration as the key step. 6,11-Dihydro-5H-benzo[a]fluorenes could be obtained from the initially generated 6,6a-dihydro-5H-benzo[a]fluorenes by subsequent heating of the reaction mixture under gold(I) or Brønsted acid catalysis or directly by conducting the reactions at high temperature.

Benzo[a]fluorene and, in particular, its polyhydro derivatives are cores frequently found in diverse natural products possessing biological activity (Figure 1). This tetracyclic skeleton is present, for instance, in isoprekinamycin,<sup>1</sup> veratramine,<sup>2</sup> or nakiterpiosinone<sup>3</sup> and is the structural base of whole families of compounds such as the dasyscyphins,<sup>4</sup> walsuchocins,<sup>5</sup> or fluostatins.<sup>6</sup>

Moreover, synthetic polyhydrobenzo[a]fluorenes have also shown interesting properties, for example, as bone loss inhibitors<sup>7</sup> or estrogen receptors.<sup>8</sup>

in recent years as a fundamental tool for the synthesis of a wide array of cyclic structures not easily prepared by conventional methodologies.9 Particularly interesting in this field are gold- and platinum-catalyzed cycloisomerizations of enynes that generally entail a rapid increase in structural complexity from readily available precursors under mild conditions.<sup>10</sup>

In this regard, we have recently described a gold-catalyzed cycloisomerization of o-alkynylstyrenes that provides an easy enantioselective access to the indene skeleton and is proposed to proceed via carbocation I (Scheme 1, via route  $a$ ).<sup>11</sup> Continuing with our ongoing interest in implementing new applications of gold-catalyzed reactions of 1,3-dien-5-ynes, $\frac{12}{12}$  we envisioned that those compounds could be appropiate substrates for the development of a new route to benzo[a]fluorene derivatives.<sup>13</sup> Thus, we considered that if a rearrangement of carbocation I by hydride migration to the adjacent carbon would be possible, the trapping of the new intermediate  $\Pi$  by intramolecular nucleophilic attack of an aromatic group could be favored (Scheme 1, via route  $b$ ). The overall transformation would therefore lead to the formation of the dihydrobenzo- [a]fluorene skeleton through a formal  $[3 + 3]$  cycloaddition.<sup>14,15</sup> The success of the proposed reaction would obviously depend on the appropiate selection of groups  $R<sup>1</sup>$  and  $R<sup>2</sup>$ , which should be able to favor the formation of carbocation II from the initially generated carbocation I.

To test our hypothesis, we selected as a model substrate o-alkynylstyrene 1a (4:1 mixture of geometrical isomers), having an isopropyl group linked to the double bond, that would generate a rather favored tertiary carbocation upon migration to form an intermediate of type II. At the outset, we tested its reactivity in the presence of different cationic gold complexes and solvents (Table 1). We were glad to find that by performing the reaction in CH<sub>2</sub>Cl<sub>2</sub> using 5 mol  $\%$ of AuPPh<sub>3</sub>Cl/AgSbF<sub>6</sub> as catalyst a high selectivity to the formation of the dihydrobenzo[a]fluorene products 2a and iso-2a was obtained, with less than 10% of indene derivatives 3a and iso-3a formed (entry 1). A minor influence of the ligand of the gold complex was observed (entries 1-4), while the counterion plays a crucial role in the outcome of the reaction (entries 1 vs 5-9) as indene derivatives 3a and iso-3a are primarily or even exclusively obtained with triflate (entry 8) or tosylate (entry 9) counterions. The solvent also has a significant influence in the selectivity of the reaction (entries 1 vs  $10-13$ ) with  $CH_2Cl_2$  being the best for promoting the formal  $[3 + 3]$  cycloaddition (entry 1), whereas ethereal solvents lead mainly to the formation of indene derivatives (entries 12 and 13). It is remarkable how an appropriate selection of the reaction conditions allows the selective isolation in good yields of either dihydrobenzo- [a]fluorene (entry 1) or indene derivatives (entry 9).

"Determined by <sup>1</sup>H NMR of the crude mixture using 1,3,5trimethoxybenzene as internal standard; isolated yield shown in parentheses.  $b$  2a was obtained as a ca. 7:1 mixture of diastereoisomers.

Thus, the best conditions for accomplishing the formal  $[3 + 3]$  cycloaddition pathway consist of the use of

Table 1. Effect of the Catalyst and the Solvent in the Selectivity

AuPPh<sub>3</sub>Cl/AgSbF<sub>6</sub> as catalyst in  $CH_2Cl_2$  as solvent. Under these conditions, we were able to isolate 80% of a ca. 7:1 mixture of 6,6a-dihydro-5H-benzo[a]fluorene 2a and 6,11-dihydro-5H-benzo[a]fluorene iso-2a, differing in the position of the double bond.<sup>16</sup>

Gratifyingly, selective formation of either 2a or iso-2a could be achieved by simply controlling the temperature of the reaction (Scheme 2a). So, 75% of 2a was isolated as a ca. 7:1 mixture of diastereoisomers<sup>17</sup> when the reaction was performed at  $0^{\circ}$ C, whereas 79% of **iso-2a** was obtained at 80 °C in DCE. These results suggest that **iso-2a** could be formed by a thermal rearrengment of 2a, which was confirmed by the transformation in good yield of isolated 2a into iso-2a upon heating under the reaction conditions or in the presence of a Brønsted acid (Scheme 2a). Moreover, we observed that when the reaction was carried out at  $80^{\circ}$ C not even traces of indene derivatives 3a or iso-3a were formed. Therefore, we checked out the possibility that indene derivatives could cyclize under these reaction conditions to afford iso-2a, which turned out to be the case (Scheme 2b). However, no transformation of 3a/iso-3a was observed in the presence of the cationic gold complex at room temperature, which is evidence that these are not intermediates in the synthesis of 2a at low temperature but the result of a different reaction pathway.

Scheme 2. Effect of the Temperature in the Selectivity

(14) It is worth noting that the unique properties of gold complexes have allowed the disclosure of new types of cycloaddition reactions that were previously unfeasible. For a recent revision on gold-catalyzed cycloaddition reactions, see: López., F.; Mascareñas, J. L. Beilstein J. Org. Chem. 2011, 7, 1075–1094.

(15) For other gold-catalyzed cycloaddition reactions involving 1,3 dien-5-ynes, see: (a) Barluenga, J.; Fernández-Rodríguez, M. A.; García-García, P.; Aguilar, E. J. Am. Chem. Soc. 2008, 130, 2764– 2765. (b) Fernández-García, J. M.; Fernández-Rodríguez, M. A.; Aguilar, E. Org. Lett. 2011, 13, 5172–5175.

(16) Variable amounts of iso-2a were obtained for all entries in Table 1 where the  $[3 + 3]$  cycloaddition pathway was observed.

(17) The relative stereochemistry of the major isomer of 2a was established by a NOESY experiment as syn. The same syn selectivity was also observed and determined for cycloadducts 2b-h as described in this paper. See the Supporting Information for details.

According to these results and based on our experience in the cycloisomerization of 1,3-dien-5-ynes we propose the following mechanism (Scheme 3).

## Scheme 3. Proposed Mechanism

The reaction would be initiated by coordination of the gold complex to the triple bond of the starting dienyne 1a followed by an intramolecular 5-endo-dig nucleophilic attack of the terminal olefin, leading to an intermediate that can be represented as the contribution of two resonance structures Ia and Ib. As previously proposed, elimination of a proton in **I** (path  $a/a'$ ) furnishes a vinyl gold intermediate that after protodemetalation gives the indene 3a or iso-3a, depending on which proton has been eliminated. On the other hand, intermediate I can undergo a hydride migration giving rise to intermediate II (path b). This new carbocation would be subsequently trapped by nucleophilic attack of the aromatic ring, a Friedel–Crafts alkylation,<sup>18</sup> affording dihydrobenzo[a]fluorene derivative III which after protodemetalation furnishes compound 2a regenerating the catalytic species.<sup>19</sup>

Once we had established the optimum conditions for directing the cycloisomerization of o-alkynylstyrenes 1 to the  $[3 + 3]$  cycloaddition pathway, we checked the potential of this methodology for the synthesis of a family of dihydrobenzo[a]fluorenes 2 and iso-2. Gratifyingly, reaction of easily accessible o-alkynylstyrenes  $1a - k$  at  $0^{\circ}C^{20}$ afforded 6,6a-dihydro-5H-benzo[a]fluorenes  $2a-k$  in good yields and with high diastereoselectivities (Table 2). The method is compatible with the presence of both a halogen (entry 1) and an electron-donating group (entry 2) in the nucleophilic aromatic ring, which can also be heteroaromatic (entry 3). Moreover, diverse substitution paterns are well tolerated at the double bond of the starting material, as long as one of the groups is a secondary alkyl

<sup>(18)</sup> For a mechanistically related gold-catalyzed reaction to give fluorenes, see: Gorin, D. J.; Watson, I. D. G.; Toste, F. D. J. Am. Chem. Soc. 2008, 130, 3736–3737.

<sup>(19)</sup> Proton elimination from intermediate II, which would lead to 3a after protodemetalation, could also be possible.

<sup>(20)</sup> Reactions of 1b,e-h occurred at rt without significant formation of iso-2 adducts, whereas increasing amounts of indenes 3 were observed at  $0^{\circ}$ C, and therefore these reactions were performed at rt.

Table 2. Synthesis of 6,6a-Dihydro-5H-benzo[a]fluorenes 2

<sup>a</sup> Isolated yield.  $\overset{b}{\phantom{a}}$  Reaction conducted at rt.  $\overset{c}{\phantom{a}}$  Obtained as a ca. 6:3:2:1 mixture of diastereoisomers.

(entries 4-7). o-Alkynylstyrenes 1i-k, having a monosubstituted olefin, are also appropriate substrates for this reaction (entries 8-10). In addition, further functionality can also be introduced in the central aromatic ring of the starting material (entry 10).

On the other hand reaction of selected  $o$ -alkynylstyrenes 1 at 80 °C allowed for the synthesis of 6,11-dihydro-5Hbenzo[a]fluorenes iso-2 with very good yields and again with a wide scope regarding the substitution in all the possible different positions (Scheme 4).

Finally, taking advantage of our previously reported enantioselective synthesis of indenes by using dinuclear chiral gold(I) catalysts, $11,21$  we explored the possibility of obtaining enantioenriched dihydrobenzo[a]fluorenes. Thus, under the best reaction conditions found,  $2^2$  we synthesized some dihydrobenzo[a]fluorenes iso-2 in an enantioselective fashion in good yields although with modest enantiomeric excess (Scheme 5).<sup>23</sup>

In conclusion, we have developed an efficient synthesis of dihydrobenzo[a]fluorenes through a novel gold-catalyzed intramolecular formal  $[3 + 3]$  cycloaddition of simple o-alkynylstyrenes. Reactions take place through a tandem 5-endo cyclization-[1,2]-hydride migration-Friedel-Crafts alkylation to afford the corresponding cycloadducts in good yields. Efforts to identify new reaction pathways

**Scheme 4.** Synthesis of 6,11-Dihydro-5H-benzo[a]fluorene<sup>a</sup>

of o-alkynylstyrenes that could provide selective and straightforward access to other relevant policyclic compounds are currently underway.
