Treatment of ynol ether-tethered dialkyl acetals with catalytic quantities of scandium triflate in CH₃CN gives rise to five-, six-, and seven-membered alkoxycycloalkene carboxylates in good to excellent yields. Tri- and tetrasubstituted carbocyclic and heterocyclic alkenes may be formed by this method, and the products obtained may serve as useful intermediates for natural product synthesis.

Alkoxycycloalkene carboxylates are highly useful starting materials for organic synthesis (Figure 1). Stereoselective introduction of carbon substituents β to the ester functional group may be accomplished by allylic substitution or Michael addition reactions, as shown by Villieras et al.¹ Ogasawara has prepared the nitraria alkaloids (+)-nitramine, (+)-isonitramine, and (-)-sibirine from 2-carboethoxy-2-cyclohexen-1-ol.² Similarly, Iwabuchi's recent synthesis of idesolide commences from 2-carbomethoxy-2-cyclohexen-1-ol.³ Lupton has also accomplished an elegant total synthesis of 7-deoxyloganin from 2-carboethoxy-2-cyclopenten-1-ol.⁴ In all cases, the hydroxycycloalkene carboxylate starting material is prepared in moderate yields by the Horner–Wadsworth– Emmons reaction of an appropriate dialdehyde with

trialkyl phosphonacetate.⁵ Since the efficiency of this protocol is often low, the development of an alternative method for the preparation of cycloalkenol carboxylates of varying ring sizes would clearly be of value for natural product synthesis. Here we report our efforts toward the realization of this goal and detail a novel Lewis acid catalyzed condensation of ynol ether-acetals that yields alkoxycycloalkene carboxylates in high yields.

Electron-rich alkynes, such as ynamines and ynol ethers, are functional groups that possess significant potential in organic chemistry for the formation of C-C bonds.⁶ Due to their linear geometry, alkynyl ethers are relatively unhindered

to approach by functional groups present in the same or different molecules; furthermore, alkynyl ethers can prospectively form up to three new bonds in a single reaction (Figure 2).

Figure 2. Reactivity of 1-alkynyl ethers and their transformation to cyclobutanones.

We have recently shown that *tert*-butyl ynol ethers bearing tethered alkenes form substituted cyclobutanones in high yields under mild thermal conditions.^{7a} In attempting to extend this method to the preparation of β -lactones and lactams through thermolysis of ketone and aldehydetethered ynol ethers, we discovered that attempted deprotection of the acetal precursors led to the formation of alkoxycycloalkene carboxylates rather than the desired carbonyl-containing ynol ethers (Scheme 1). Thus, treatment of acetal **2aa** (prepared from aldehyde **1a** by addition of *tert*-butoxyethynyllithium^{7b} and silyl protection of the resulting propargylic alcohol) with 5 mol % I_2 in acetone⁸ at rt for 5 min gave rise to silyloxycycloalkene carboxyate **3aa** in 45% yield, as well as a 1:1 mixture of the more polar methyl esters **3ab** and **3ac** in 40% yield. Interestingly, treatment of ethyl alkynyl ether **2ab** with Sc(OTf)₃ in CH₃CN led to the formation of ethyl ester **3ad** cleanly in 80% yield; however, addition of up to 15 mol % of catalyst was necessary in order to achieve optimal conversion of **2ab** to **3ad**. On large scale (> 500 mg), the increased amounts of Lewis acid catalyst required led to side products arising from cleavage of the silyl ether protecting group and lower (60–70%) yields of **3ad**.

These initial results prompted us to evaluate the use of other Lewis acids to catalyze the apparent cyclocondensation process (Table 1). Addition of Sc(OTf)₃ (5 mol %) to substrate **2aa** in CH₃CN gave a 78% yield of **3aa** within 5 min at room temperature with only trace amounts of **3ab** and **3ac** formed. In(OTf)₃^{9a} and Zn(OTf)₂ also provided **3aa**, although in significantly lower yields (50% and 25%, respectively); moreover, complete consumption of **2a** was never achieved, even with the addition of excess catalyst (up to 15 mol %) to the reaction mixture.

Treatment of **2aa** with the Lewis acids AgOTf or BiCl₃^{9b} in CH₃CN led to significant amounts of substrate decomposition, with only minute quantities (< 5%) of **3aa** recovered from the reaction mixtures. In contrast, no reaction occurred when **2aa** was stirred in the presence of InCl₃, even after 1 h. Finally, treatment of **2a** with 5 mol % TMSOTf in CH₂Cl₂ at -78 °C gave **3aa** in 70% yield after silica gel chromatography.

A possible mechanistic pathway for this process (Scheme 2) might involve Lewis acid coordination of the acetal oxygen atom, followed by ionization and [2 + 2] cycloaddition. Loss of isobutylene accompanied by ring opening would then furnish either unsaturated methyl ester **3aa** or ketene **A**. A methanol trap of **A** would provide **3ac**; Lewis acid

mediated allylic substitution of **3aa** with the liberated methanol molecule could give rise to **3ab**. Ester **3ac** does not convert into **3aa** upon prolonged exposure to Lewis acid; however, extended reaction times and/or the addition of excess Lewis acid results in the conversion of unsaturated ester **3aa** into methyl ether **3ab**. A similar pathway from **2ab** to **3ad** could proceed through S_N 2-like cleavage of the oxonium methyl group, followed by pericyclic ring opening of the oxetene intermediate (Scheme 3).¹⁰

To explore the scope of this process, substrates 2b-2g(Table 2) were prepared in a similar fashion (see Supporting Information (SI))¹² and treated with catalytic amounts of a Lewis acid at rt or -78 °C. While scandium triflate was an effective Lewis acid for ketone-derived acetals, TMSOTf proved to be similarly efficient for aldehyde derived acetals. Five- (entries 1–4) and six- (entries 5–7)

⁽¹²⁾ Substrates 2a-2g were obtained from the corresponding 1,4- or 1,5-oxocarboxylic acids in 40–61% overall yields. See SI.

Scheme 4. Requirements for Seven-Membered Ring Formation

membered rings may be prepared in good to excellent yields in this manner. Furthermore, both trisubstituted (entries 3 and 7) and tetrasubstituted (entries 1, 2, and 4–6) cycloalkenes are formed with similar efficiencies. Silyl protecting groups employed in cyclization substrates **2** include TBS (entry 2) and TBDPS (*tert*-butyldiphenylsilyl, entries 1 and 3–7) and are necessary to avoid the facile Meyer–Schuster rearrangement¹¹ that is observed for the corresponding propargylic alcohols under Lewis acidic reaction conditions. It was subsequently discovered (Table 3, entry 2) that protection of tertiary propargylic alcohols as their methyl ethers was also suitable for the cyclocondensation process (*vide infra*).

Extension of this chemistry to the synthesis of sevenmembered alkoxycycloalkene carboxylates was also possible. While substrate **2h** disappointingly gave only a 5:1 mixture of acyclic ketoester 4 and unsaturated ester 5 upon exposure to catalytic quantities of scandium triflate, under the same conditions diethylacetal 2i gave a 72% yield of the expected ethyl ester 3i (Scheme 4). From these data it appears that substrate preorganization to allow the proximity of the ynol ether and acetal termini is important for successful application of this method to the synthesis of medium-ring containing products. Table 3 shows several additional examples of the preparation of trisubstituted (entries 1-3, 5) and tetrasubstituted (entry 4) cycloalkenes containing 5-7 and 6-7 ring systems utilizing this methodology. Seven-membered cyclic ethers such as 3i may be prepared containing a tertiary methyl ether (entry 2). Moreover, fused 5-7 ring systems similar to that found in guaiane-type sesquiterpene natural products (3m, entry 5)

(13) Compound **2i** was prepared in 41% overall yield from 2-bromobenzaldehyde diethylacetal. See SI and (a) Mukherjee, A.; Liu, R.-S. *Org. Lett.* **2011**, *13*, 660. (b) Sajiki, H. *Tetrahedron Lett.* **1995**, *36*, 3465.

(14) Compound **2j** was prepared in 53% overall yield from salicylaldehyde. See SI and: Martinez-Peragon, A.; Millan, A.; Campana, A. G.; Rodriguez-Marquez, I.; Resa, S.; Miguel, D.; Alvarez de Cienfuegos, L.; Cuerva, J. M. *Eur. J. Org. Chem.* **2012**, *8*, 1499.

(15) Compound **2k** was prepared in 35% overall yield from 2-allylcyclohexanone. See SI and: Asao, N.; Lee, S.; Yamamoto, Y. *Tetrahedron Lett.* **2003**, *44*, 4265.

(16) Compound **21** was prepared in 22% overall yield from 2-allylcyclohexanone. See SI and: Smith, A. B.; Cho, Y. S.; Friestad, G. K *Tetrahedron Lett.* **1998**, *39*, 8765.

(17) Compound **2m** was prepared in 29% overall yield from 2-allylcyclopentanone. See SI. Table 3. Preparation of Seven-Membered Cycloalkenes^a

^{*a*} Reaction conditions: 0.33 M 2 in CH₃CN, Sc(OTf)₃ (10 mol %), rt, 10 min. ^{*b*} For preparation of 2i–2m, see SI and refs 13–17. ^{*c*} Isolated yield after column chromatography. ^{*d*} Compounds 2k, 2l, 3k, and 3l are composed of a 2:1 mixture of diastereomers. See text and refs 15 and 16. ^{*e*} Compounds 2m and 3m are composed of a 3:1 mixture of diastereomers. See text and ref 17.

could also be synthesized in moderate yields. Compounds 2k-2m and 3k-3m were obtained as a mixture of diastereomers (2:1 for 2k, 2l, 3k, and 3l, and 3:1 for 2m and 3m) resulting from the low stereoselectivity of the addition of (ethoxyethynyl)lithium to the corresponding aldehyde precursors.

In summary, we have shown that acetal-tethered alkynyl ethers undergo facile intramolecular condensation reactions under Lewis acid catalysis to form 5, 6, and 7-membered alkoxycycloalkene carboxylates, compounds which are useful intermediates for natural product synthesis. We are currently exploring methods for the preparation of optically enriched cycloalkene carboxylates from the asymmetric addition of alkynyl ether anions to aldehyde and ketones, and the results of this study will be reported in due course.
