Organic Reactions, Volume 56

Larry E. Overman (Editor-in-Chief)

ISBN: 978-0-471-39568-3

696 pages

October 2000

Organic Reactions is a comprehensive series of volumes devoted to important synthetic reactions. For each volume, the authors are world-renowned experts with extensive hands-on experience in the field. The subjects are presented from the preparative viewpoint, and particular attention is given to limitations, interfering influences, effects of structure, and the selection of experimental techniques.

Each chapter includes detailed procedures illustrating the significant modifications of the chemical reaction, as well as tables listing all the pertinent examples of the reaction. The topics discussed in Volume 56 are the Hydroformylation reaction and the Vilsmeier reactions of non-aromatic compounds. Each reaction is presented with information about the reaction conditions, products, and yields where available, and is fully referenced to the primary literature.

INTRODUCTION

The reaction of 1-alkenes with carbon monoxide and hydrogen in the presence of a catalyst gives the corresponding homologous aldehydes (Eq. 1). The discov-

ery of this reaction was made by Roelen in 1938 using $\text{Co}_2(\text{CO})_8$ as the catalyst at high temperature (120–170°) and high pressure of carbon monoxide/hydrogen (200–300 bar).^{1,2} This reaction has been called the “Oxo reaction”, “Roelen reaction” or “hydroformylation”.^{3,4} Hydroformylation is a general term indicating that both a hydrogen and a formyl group are introduced to unsaturated bonds, especially olefins.

Later this reaction was developed as an industrial process, i.e., the Oxo Process, for the production of alkanals from 1-alkenes using a cobalt or rhodium catalyst.^{3,4} Most noteworthy is the conversion of propene to butanal, which can be subsequently hydrogenated to 1-butanol or converted to 2-ethylhexanol by self-aldol condensation.^{3,4} 2-Ethylhexanol, a crucial intermediate for the production of ester-type plasticizers, is the most important bulk chemical produced by the Oxo Process.^{3,4} A variety of transition metal catalysts other than $\text{Co}_2(\text{CO})_8$ have been investigated, including phosphine complexes of cobalt and hydridocobalt clusters. Platinum and ruthenium complexes show reasonably good catalytic activities, but modified cobalt catalysts are still much more advantageous. However, various rhodium complexes demonstrate higher catalytic activity (10^3 – 10^4 times) than the cobalt complexes. Although the price of rhodium is higher than cobalt, reactions using rhodium catalysts require lower temperature (50–80°) and pressure (10–50 atm).

Other important commercial applications of hydroformylation include the production of long-chain alcohols from C_5 – C_{17} isomeric linear alkenes.^{3–5} These long-chain alcohols serve as intermediates for lubricants, plasticizers and detergents.⁵ The hydroformylation of ethene to propanal is another important Oxo Process.⁵

Excellent reviews appeared in 1970s^{6–9}, 1980s^{3,4,10–15} and 1990s.^{16–19} An exhaustive review of the Oxo Processes of 1-alkenes and other hydroformylation reactions appeared in 1980 and covered all aspects of the hydroformylation reaction from its discovery to 1978.³

In this chapter, the authors put clear emphasis on the scope of the hydroformylation reaction in organic synthesis. In this context, there is a relevant review in 1987 of the hydroformylation of functionalized alkenes.⁵ The hydroformylation reaction now can be performed under very mild conditions using a variety of functionalized alkenes.²⁰ Reactions in aqueous biphasic,^{21–23} supercritical carbon dioxide^{24–30} or fluorous biphasic^{31,32} have recently emerged in response to separation and environmental issues. In fact, a highly efficient Oxo Process using a water-soluble rhodium catalyst, $\text{HRh}(\text{CO})(\text{TPPTS})_3$ [TPPTS = $\text{P}(\text{C}_6\text{H}_4\text{SO}_3\text{Na-}m)$], in aqueous biphasic conditions has been commercialized by Ruhrchemie/Rhône-Poulenc for the production of butanal.^{21–23} Asymmetric hydroformylation of prochiral olefins catalyzed by enantiopure rhodium complexes has been developed to the level that practical applications appear possible.^{33–42} Although the reactions of formaldehyde, oxiranes, and others with carbon monoxide and hydrogen in the presence of transition metal catalyst could be considered as variations of hydroformylation, this chapter only deals with hydroformylation of carbon-carbon multiple bonds.

MECHANISM

Extensive mechanistic studies have been performed on the cobalt-catalyzed hydroformylation of olefins. Studies of the mechanism of hydroformylations catalyzed by rhodium and platinum complexes, which were developed later, greatly benefited from the accumulated knowledge on the cobalt counterpart. The rapid advances in organometallic chemistry in the 1960s and 1970s also made significant contributions to the detailed understanding of the individual steps involved in this reaction. Direct observation of reactive intermediates by high pressure IR spectroscopy helped confirm catalytic cycles proposed on the basis of kinetics. Deuterium labeling provides important information about a possible equilibrium between the starting olefin, intermediates, and products, which is useful for the determination of the rate-determining step.^{4,43-51} ^1H , ^{13}C , and ^{31}P NMR spectroscopies (and ^{195}Pt NMR for platinum catalysts) have been extensively used for direct observation and structural characterization of reactive intermediates.^{34,52-62} Theoretical studies on the energy analysis of possible intermediates in the catalytic cycle have been advanced to give more insight into and better understanding of the mechanism of hydroformylation.⁶³⁻⁶⁶

These mechanistic studies have established the crucial unit processes involved in the hydroformylation of olefins, although some mechanistic details await further investigation.^{3,4,64} It has been shown that there are three crucial unit processes: (1) reaction of a hydrido-metal species with an olefin to form an alkyl-metal species, (2) alkyl migration to a carbonyl ligand of the metal, i.e., net carbon monoxide insertion to the alkyl-metal bond ("migratory insertion"), forming an acyl-metal species, and (3) hydrogenolysis of the acyl-metal species, giving an aldehyde and regenerating the hydrido-metal species.

Cobalt-Catalyzed Hydroformylation

The generally accepted mechanism for the hydroformylation of olefins catalyzed by $\text{Co}_2(\text{CO})_8$ was first proposed by Heck and Breslow⁶⁷ and is depicted in Scheme 1 for the formation of a linear aldehyde. The proposed mechanism includes the generation of $\text{HCo}(\text{CO})_4$ from $\text{Co}_2(\text{CO})_8$ and hydrogen as the first step, followed by the three crucial unit processes mentioned above. Instead of hydrogenolysis of the acyl-cobalt species, $\text{RCH}_2\text{CH}_2\text{CO-Co}(\text{CO})_4$, reductive cleavage of the acyl-cobalt species with $\text{HCo}(\text{CO})_4$ is also possible to regenerate $\text{Co}_2(\text{CO})_8$.

A series of carefully designed model reactions, simulations, analogies with stoichiometric reactions, kinetic and IR spectroscopic studies at the same temperature and pressure as those of the industrial Oxo Process confirmed the validity of the Heck-Breslow mechanism with some modifications.^{3,4} For instance, IR spectroscopic studies under industrial Oxo Process conditions have revealed the virtually complete conversion of $\text{Co}_2(\text{CO})_8$ (**1**) to $\text{HCo}(\text{CO})_4$ (**2**).⁶⁸ Although the formation of alkyl- and acyl-cobalt carbonyl complexes can be observed in model reactions, no alkyl-cobalt complexes have been detected under the conditions of the industrial process, i.e., only acyl- $\text{Co}(\text{CO})_4$ **8** is observed.⁶⁹⁻⁷¹

In the Heck-Breslow mechanism, formal reductive cleavage of the acyl-Co complex **8** with molecular hydrogen or $\text{HCo}(\text{CO})_4$ (**2**) is proposed. However, it is more than likely that the actual acyl-Co complex that reacts with molecular hydrogen is the coordinatively unsaturated (16-electron) acyl-Co(CO)₃ **7**, and the oxidative adduct **10** is formed from **7**, which then reductively eliminates to give aldehyde and $\text{HCo}(\text{CO})_3$ (**3**) (Scheme 1).^{4,43}

With regard to the two possible mechanisms for the formation of aldehyde from the acyl-Co complex **8**, it is still not certain which one is operating under catalytic conditions although either one can take place under stoichiometric conditions. Supporting evidence for the hydrogenolysis route^{72,73} as well as the bimolecular route involving $\text{HCo}(\text{CO})_4$ (**2**)⁷⁴⁻⁷⁷ has been presented.

Although Scheme 1 shows only the formation of a linear aldehyde, a mixture of linear (major) and branched (minor) aldehydes is obtained in the hydroformylation of 1-alkenes (Scheme 2). The regioselectivity of this reaction should be determined at the alkyl-Co complex formation step (**4** \rightarrow **5** or **6**) and/or the subsequent acyl-Co complex formation step (**6** \rightarrow **7** or **8**). The *stoichiometric* hydroformylation of 1-propene in the absence of free carbon monoxide gives 70% branched aldehyde $(\text{CH}_3)_2\text{CHCHO}$ and 30% linear aldehyde $\text{CH}_3(\text{CH}_2)_2\text{CHO}$,^{3,78-80} which appears to be consistent with the Markownikow rule since $\text{HCo}(\text{CO})_3$ is a strong acid. This result indicates that regioselectivity is determined at the alkyl-Co

Scheme 2

complex formation step ($\mathbf{4} \rightarrow \mathbf{5}$) under these conditions. However, the stoichiometric reaction *in the presence of* free carbon monoxide as well as the *catalytic* reaction exhibit reversed regioselectivity, i.e., the reactions give 70% linear aldehyde and 30% branched aldehyde.^{3,81} The results clearly indicate that acyl-Co complex formation ($\mathbf{6} \rightarrow \mathbf{8}$) is the regioselectivity-determining step, i.e., the migratory insertion should be easier for the linear alkyl-Co(CO) complex than that for the branched counterpart mainly for steric reasons ($k_{lco} > k_{bco}$). Under optimized conditions (110°, 150 bars, $\text{H}_2:\text{CO} = 1$), a linear/branched aldehyde ratio of 4/1 is achieved in the hydroformylation of 1-propene.³

One factor that complicates the mechanistic understanding of this reaction is the fact that the olefin-Co, alkyl-Co and acyl-Co complexes are in equilibrium. The existence of equilibrium among these intermediate complexes is consistent with the observations of (1) olefin isomerization^{3,82-87} and (2) virtually statistical isotope scrambling on using 1,1,2-trideuterio-1-propene,^{79,80} 6,6,6-trideuterio-1-hexene⁷⁹ or 1-[¹⁴C]-propene.⁸¹ Isomerization and isotope scrambling are suppressed at high carbon monoxide pressures (>100 bars) and temperatures up to 140°. ^{3,4,6,84} This fact clearly indicates that vacant coordination sites are necessary for the observed isomerization and isotope scrambling. These observations are also consistent with kinetic studies.^{3,88,89}

When the enantiomerically enriched alkene (*S*)-3-methyl-1-hexene is employed, 3-ethyl-1-hexanal is formed with 70% retention of configuration together with 4-methyl-1-heptanal and 2,3-dimethyl-1-hexanal, in spite of the fact that the precursor of this product should be achiral 2-ethyl-1-pentene generated through isomerization of (*S*)-3-methyl-1-hexene.^{82,90-92} In order to accommodate this result, a 1,2-hydrogen shift mechanism has been proposed that does not include a true σ carbon-Co bond and is faster than the dissociation of olefin from the olefin-Co complex, which appears to be generally accepted.^{3,4,6,90}

A variety of ligand-modified cobalt catalysts have been investigated³ and a commercial process known as the Shell Process was developed^{3,93-95}. The Shell Process uses tributylphosphine as the modifier, which generates $\text{HCo(CO)}_3\text{PBu}_3$ as the active catalyst species^{68,96} and is substantially more stable than HCo(CO)_4 . This process gives a higher linear/branched ratio (7.3/1, i.e., 88% linear and 12% branched for the reaction of 1-propene), but the products are alcohols and not aldehydes, and ca. 15% of 1-propene is hydrogenated to propane. These

characteristics may be ascribed to steric and electronic effects of the bulky and electron-donating phosphine ligand.

Rhodium-Catalyzed Hydroformylation

Mechanistic studies of rhodium-catalyzed hydroformylation of olefins have shown that the basic feature of the catalyst cycle is more or less the same as that of the cobalt-catalyzed reaction.^{3,4} When unmodified rhodium carbonyls, e.g., $\text{Rh}_4(\text{CO})_{12}$ and $\text{Rh}_6(\text{CO})_{16}$, are used as catalysts, there is an equilibrium among $\text{Rh}_4(\text{CO})_{12}$, $\text{Rh}_6(\text{CO})_{16}$, and $\text{HRh}(\text{CO})_n$ ($n = 3$ or 4) in the presence of carbon monoxide and hydrogen, which complicates the mechanistic study.^{3,4} Nevertheless, $\text{HRh}(\text{CO})_n$ ($n = 3$) is postulated as the active catalyst species,^{3,4,9} and the formation of $\text{HRh}(\text{CO})_4$ is observed by FT-IR analysis.⁹⁷

Although the unmodified rhodium carbonyl catalyst $\text{HRh}(\text{CO})_n$ shows high activity, it gives a low regioselectivity and tends to hydrogenate or isomerize olefins,³ i.e., this catalyst is not practically useful.

Most mechanistic studies on ligand-modified rhodium catalysts have been performed using $\text{HRh}(\text{CO})(\text{PPh}_3)_3$,^{3,4} which was introduced as a hydroformylation catalyst in 1968.^{98,99} These extensive mechanistic studies on the basis of IR, ^1H and ^{31}P NMR spectroscopies have revealed that $\text{HRh}(\text{CO})_2(\text{PPh}_3)_2$ (**11**) (an 18-electron species, generated by losing one triphenylphosphine ligand from $\text{HRh}(\text{CO})(\text{PPh}_3)_3$ and acquiring one carbon monoxide ligand) is a key active catalyst species, which readily reacts with ethylene at 25° .⁹⁹ Two mechanisms, an associative pathway and a dissociative pathway, were proposed,^{3,6,99,100} depending on the concentration of the catalyst (Scheme 3, only the formation of a linear aldehyde is shown for clarity).

According to the proposed mechanisms, the associative pathway (A) dominates at catalyst concentrations $>6 \times 10^{-3}$ mol/L, while the dissociative pathway

Scheme 3

(D) that includes the generation of a more active catalyst species, $\text{HRh}(\text{CO})_2(\text{PPh}_3)$ (**12**), through loss of another triphenylphosphine ligand becomes predominant at concentrations $< 6 \times 10^{-3}$ mol/L.⁹⁹ The fact that carbon monoxide and excess triphenylphosphine inhibit the reaction⁹⁹ strongly suggests formation of the pentacoordinated acyl-Rh species **16** (18-electron species) that does not react with molecular hydrogen because of the lack of a vacant coordination site for molecular hydrogen to undergo oxidative addition.^{4,43} Under the industrial reaction conditions producing *n*-butanal from propene with high selectivity, the use of a large excess of triphenylphosphine is required, which certainly favors the associative pathway. In the associative pathway, it was originally assumed that coordination of an olefin to $\text{HRh}(\text{CO})_2(\text{PPh}_3)_2$ (**11**) would take place to generate a hexacoordinated 20-electron π -olefin-Rh species.^{4,101} However, this appears to be unlikely based on the generally accepted 18-electron rule.^{43,102} Thus, a modified mechanism that can accommodate these points has been proposed as shown in Scheme 4.⁴³ In this mechanism, (1) coordinatively unsaturated $\text{HRh}(\text{CO})(\text{PPh}_3)_2$

Scheme 4

(**18**) (16-electron species) is generated from **11**, and **18** is the active catalyst, (2) **18** forms the π -olefin-Rh complex **19** (18-electron species), (3) **19** gives the alkyl-Rh complex **20** (16-electron species), (4) carbon monoxide coordinates to **20** to form the saturated alkyl-Rh complex **21**, (5) a migratory insertion takes place to give the unsaturated acyl-Rh complex **17**, (6) oxidative addition of molecular hydrogen to **17** gives the acyl-Rh dihydride complex **22** (18-electron species), and (7) a reductive elimination takes place to give an aldehyde and regenerate **18**.

Although Scheme 4 shows only linear alkyl-Rh and acyl-Rh intermediates (**20-l**, **21-l**, **17-l**, and **22-l**), the branched counterparts of these intermediates (**20-b**, **21-b**, **17-b**, and **22-b**) as well as branched aldehyde $\text{R}(\text{CH}_3)\text{CHCHO}$ should be formed when the alkyl-Rh complex formation step yields the branched alkyl-Rh intermediate, $\text{R}(\text{CH}_3)\text{CH-Rh}(\text{CO})(\text{PPh}_3)_2$ (**20-b**), that follows the same subsequent steps as those discussed above (see also Scheme 2). The fact that excess

triphenylphosphine decreases the reaction rate, but increases the linear/branched ratio of the resulting aldehyde and suppresses hydrogenation and rearrangement of olefin, indicates that the regioselectivity of the reaction is determined in the step that forms the alkyl-Rh complex from the π -olefin-complex **19**.⁴³

For reductive cleavage of acyl-Rh complex **17**, it is generally accepted that molecular hydrogen is the hydrogen donor as shown in Scheme 4. However, this step could be effected alternatively by another hydrido-Rh complex, $\text{HRh}(\text{CO})_2(\text{PPh}_3)_2$, in a manner similar to that discussed for the cobalt-catalyzed reaction. With regard to this possibility, intriguing results have been reported: (a) silica-bonded rhodium complexes are found to be inactive when these complexes are completely site isolated, whereas these complexes become active when the site isolation is such that only a pair of rhodium complexes are close enough to undergo the bimolecular reductive cleavage of an acyl-Rh complex by a hydrido-Rh complex;¹⁰³ (b) a homogeneous binuclear rhodium complex with a specially designed tetraphosphine ligand, that places two rhodium metals in an appropriate space so that the bimolecular reductive cleavage is feasible, shows exceptional acceleration of the reaction rate.^{104,105} Although these findings cannot eliminate the generally accepted reductive cleavage step with molecular hydrogen, it is strongly indicated that bimolecular reductive cleavage involving two rhodium species is operative under certain reaction conditions.

Ab initio molecular orbital studies on the whole catalytic cycle of hydroformylation of ethylene catalyzed by $\text{HRh}(\text{CO})_2(\text{PH}_3)_2$ has been performed,^{63,64} which points out the significance of the coordinating solvent, ethylene in this case, and identifies the oxidative addition of molecular hydrogen to the pentacoordinate acyl-Rh complex (**17** \rightarrow **22**) as the rate-determining step. In fact, this step is the only endothermic process in the catalytic cycle.

As discussed above, kinetic studies on the effect of partial pressures of hydrogen and carbon monoxide on the reaction rate indicate that the oxidative addition of molecular hydrogen to the Rh complexes with phosphine^{3,43} or diphosphite⁵⁵ ligands is the slowest step in the whole process. Further mechanistic studies, however, have revealed that the rate-determining step of the reaction depends on the nature of the ligand employed, and in some cases alkene insertion into the Rh-H bond becomes the slowest step as observed for the Rh-BINAPHOS-catalyzed reactions.⁵¹ It has also been shown that alkene insertion to the Rh-H bond is irreversible for the formation of linear alkyl-Rh species in general, while this step may become reversible for the formation of branched alkyl-Rh species, depending on the reaction conditions and the nature of the alkene.⁵¹

It has been shown that hydrometalation of the olefin (step 3: **19** \rightarrow **20**) proceeds by complete *cis* addition, and the subsequent migratory insertion of carbon monoxide (step 4: **21** \rightarrow **17**) takes place with retention of configuration.^{4,43-45,106} Thus, the hydroformylations of (*E*)- and (*Z*)-3-methyl-2-pentenes give *syn*- and *anti*-2,3-dimethylpentanals, respectively, in a stereospecific manner (Eqs. 2 and 3).^{4,44} Some *E-Z* isomerization of the olefins takes place during the reaction, complicating the analysis, but deuterium labeling experiments reveal the completely stereospecific *cis*-addition of hydrogen and a formyl group to the double bond.^{4,43-45}

Asymmetric Hydroformylation

When an appropriate chiral ligand is introduced to a catalyst, the differentiation of two enantiofaces of a prochiral olefin is conceptually possible in the hydroformylation reaction. There are three classes of alkenes from which enantiomerically enriched aldehydes can be obtained (Eqs. 4–6). The asymmetric hy-

droformylation of 1-alkenes to give the corresponding branched aldehydes regioselectively and enantioselectively (Eq. 4) is the most general process, but it is more complicated than the other two ways (Eqs. 5 and 6) because of the formation of achiral linear aldehydes in substantial amounts as undesirable products.

Extensive mechanistic studies have been performed on reactions catalyzed by rhodium and platinum complexes containing enantiopure C_2 -symmetric diphosphine ligands.^{54,107–112} As discussed above, (1) the formation of the π -olefin-Rh(H) complex **19**, (2) stereospecific *cis* addition of the hydridorhodium to the coordinated olefin to form the alkyl-Rh complex **20** (and then **21**), and (3) the migratory insertion of a carbonyl ligand giving the acyl-Rh complex **17** with retention of configuration, have been established in the hydroformylation of 1-alkenes or substituted ethenes. Thus, it is reasonable to assume that the enantioselectivity of the reaction giving a branched aldehyde is determined at the diastereomeric (1) π -olefin-Rh complex **19** formation step, (2) alkyl-Rh complex **20** formation step, or (3) acyl-Rh complex **17** formation step.

As Scheme 5 illustrates, when a 1-alkene reacts with hydridorhodium complex with a chiral diphosphine ligand **18***, two diastereomeric π -olefin-Rh complexes,

Scheme 5

19*-S and **19*-R**, are formed, in which the *Si* face and *Re* face of the 1-alkene coordinate to the Rh catalyst, respectively. The π -olefin-Rh complex, **19*-S** has two rotamers, **19*-bS** and **19*-lS**, that are relevant to the *cis* addition of the hydridorhodium. The π -olefin-Rh complex **19*-bS** gives the branched (*S*)-aldehyde via the alkyl-Rh complex **20*-bS** and the acyl-Rh complex **17*-bS**, whereas **19*-lS** leads to the formation of the linear achiral aldehyde. In the same manner, the π -olefin-Rh complexes **19*-bR** and **19*-lR** give the branched (*R*)-aldehyde and the linear achiral aldehyde, respectively.

Based on the apparent importance of the relative population of the four isomers of the π -olefin-Rh complexes **19*** in determining enantioselectivity as well as regioselectivity, an empirical rule was proposed for prediction of the absolute configuration of the major aldehyde and regioselectivity in the asymmetric hydroformylation of prochiral olefins catalyzed by rhodium and platinum complexes with C_2 -symmetrical chiral diphosphine ligands.^{107,108,111} This simple quadrants model assumes the trigonal bipyramidal configuration of π -olefin-M

complex **19*** (M = Rh or Pt) in the transition state of the alkyl-Rh complex formation (early transition state model) and defines the large (L) and small (S) ligands based on experimental results in a consistent manner (Z = CO). This model was successfully applied to the reactions of simple aliphatic olefins such as butenes, 2-methyl-1-butene, 2,3-dimethyl-1-butene, and norbornene. However, this model failed to give meaningful explanation and prediction for the reactions of unsaturated esters and vinylarenes such as styrene and 2-phenylpropene.

Another crucial step for asymmetric induction is the formation of alkyl-M complex **20***; i.e., the rate of olefin insertion to the M-H bond should be different in each π -olefin-M complex **19*** and this difference should be reflected in the final ratio of two enantiomeric aldehydes.³³ This possibility should be examined in the future.

Most of the molecular models for the mechanistic studies of asymmetric hydroformylation catalyzed by C₂-symmetric chiral diphosphine-Rh complexes are based on a trigonal bipyramidal structure in which two phosphorus atoms occupy equatorial positions as exemplified in **19***. In fact, recent NMR and X-ray crystallographic studies on HRh(CO)₂(diphosphite) complexes support this type of trigonal bipyramidal structure.⁵⁵⁻⁵⁸ However, a different trigonal bipyramidal structure plays a key role in the hydroformylation of prochiral olefins (e.g., 94% ee for styrene, b/l = 88/12; 97% ee for (*E*)-1-phenyl-1-propene, b/l = 97/3) catalyzed by a rhodium complex with a phosphine-phosphite chiral ligand, BINAPHOS.³⁴ It has been shown, on the basis of NMR and IR data, that HRh(CO)₂(BINAPHOS) complex (**23**) takes a trigonal bipyramidal configuration in which the phosphine moiety occupies an equatorial position and the phosphite moiety as well as the hydride apical positions.^{34,113} A recent molecular modeling study has indicated that the outstanding properties of BINAPHOS can be ascribed to a combination of the unique coordination mode, adequate numbers of

23

Rhodium complexes with a bis(diphenylmethyl)norbornane **28**,²⁴⁷ a bis(dioxaphospholane) **29**,^{248,249} and α,α -TREDIP (**30**)²⁵⁰ as well as a zwitterionic rhodium-borate complex **31**²⁵¹ give 2-phenylpropanal with 97–99% selectivity in the hydroformylation of styrene (Eq. 9).

Dienes and Polyenes

The hydroformylation of conjugated dienes such as 1,3-butadiene, isoprene, and 1,3-pentadiene gives mixtures of regioisomers, isomerized aldehydes, and dialdehydes depending on the conditions and catalysts used.²⁵²⁻²⁵⁶ The reaction of 1,3-butadiene provides 1,6-hexanedial and has relevance to nylon production.^{257,258} The reaction of 1,3-cyclohexadiene catalyzed by a rhodium complex gives a 9:1 mixture of regioisomers (Eq. 10). Recently, high regioselectivity as well as enantioselectivity has been accomplished in the asymmetric hydroformylation of 1,3-dienes.

With nonconjugated dienes, the terminal olefin moiety reacts preferentially with both Pt and Rh catalyst systems (Eqs. 11, 12).²⁵⁹⁻²⁶⁴ The reaction of (*E, E, Z*)-cyclododeca-1,5,9-triene gives two regioisomers (Eq. 13).²⁶⁵

The hydroformylation of alkynes is usually accompanied by extensive hydrogenation, producing saturated aldehydes or alkenes. However, the use of bimetallic catalytic systems, such as Pd-Co, Pd-W or Pd-Fe, can achieve excellent yields in the hydroformylation of symmetric internal alkynes, affording conjugated unsaturated aldehydes (Eq. 14).²⁶⁶

Functionalized Olefins

Functionalized alkenes. Regioselective hydroformylation of functionalized alkenes has been extensively studied.^{5,135,267-286} The rhodium complex with BIPHEPHOS (**25**) is an excellent catalyst for regioselective hydroformylation of functionalized terminal alkenes to give aldehydes (Eq. 15).¹³⁵ A zwitterionic

X = MeCO-, MeOC(O), PhC(O)OC(O), Et₂NCO, (EtO)₂CH, (CH₂CO)₂N; n = 0 to ∞

rhodium complex, [Rh(DPPB)(COD)]|[BPh₄] (DPPB = Ph₂P(CH₂)₄PPh₂), is also a good catalyst for the reaction of allyl alcanoates, yielding aldehydes with 91–95% regioselectivity.^{267,287}

Functional group-directed hydroformylation. Phosphine and phosphite moieties in olefinic substrates exert strong directing effects on the regioselectivity of hydroformylation. For example, hydroformylation of 4-(diphenylphosphino)-1-butene (**32**) catalyzed by Rh₂(OAc)₄/4PPh₃ gives branched aldehyde **33**, which subsequently is reduced to provide the corresponding alcohol **34** as the sole product (Eq. 16).^{288,289} Under the same conditions, 1-hexene affords the linear alde-

hyde as the major product. Similar strong directing effects of a phosphite moiety are observed in reactions of cyclic and acyclic alkenylphosphites, e.g., cyclohex-

enyl phosphite **35** is converted to *cis*-1,2-bis(hydroxymethyl)cyclohexane (**37**) with 100% regio- and stereoselectivity after reduction of the intermediate aldehyde **36** (Eq. 17).^{290,291} The use of phosphite as an intramolecular directing group

is attractive for organic syntheses since the phosphite moiety can be easily introduced and then readily removed after regioselective hydroformylation. Intramolecular phosphine-directed hydroformylation has been successfully applied as a key step in the synthesis of (+)-phyllanthocin (Eq. 18).²⁹²

Hydroxy-directed hydroformylation of (20*R*)-3β-dihydroxypregna-5,16-diene (**40**) catalyzed by $\text{Rh}_2\text{Cl}_2(\text{NBD})_2/\text{PBu}_3/\text{NEt}_3$ gives 16α-aldehyde **41** in 80% yield after recrystallization (Eq. 19).²⁹³

Alkenyl and Alkynyl alcohols. Rhodium-catalyzed hydroformylation of unsaturated alcohols provides useful intermediates for organic syntheses.^{294–312} For example, hydroformylation of homoallylic alcohols gives isolable lactols **42**,³¹³ which can be oxidized to the corresponding lactones **43** (Eq. 20).³¹⁴ The

propargyl alcohol moiety of steroid **44** reacts selectively to give lactol **45** with the trisubstituted olefin left intact (Eq. 21).⁷⁴⁸

As an approach to the synthesis of aldols, hydroformylation of (*Z*)- β -silylallyl alcohols **46** catalyzed by $\text{RhH}(\text{CO})(\text{PPh}_3)_3/\text{PPh}_3$ gives **47** with high regioselectivity (>98%) (Eq. 22).³¹⁵

Alkenyl esters. Hydroformylation of vinyl acetate gives exclusively the branched aldehyde **49** (Eq. 23)³¹⁶⁻³¹⁸, while the linear aldehyde **50** is the predominant product in the reaction of allyl acetate (Eq. 24)²⁶⁷.

α,β -Unsaturated esters. Hydroformylation of α,β -unsaturated esters and diesters generally gives α -formyl esters,³¹⁹⁻³²³ but with some exceptions.³²⁴ Hydroformylation of ethyl acrylate is catalyzed by the $\text{Rh}_2\text{Cl}_2(\text{CO})_2$ /phosphine/ NEt_3 system under mild conditions (20–40°, H_2/CO (1/1, 20 atm) to give ethyl 2-formylpropanoate (**52**) with high regioselectivity (98–100%) (Eq. 25).³¹⁹ A

phosphole (*o*-TDPP) (**53**), a phosphanorbornadiene (DMTPPN) (**54**), and DPPB are particularly effective ligands for this reaction. Regioselectivity of hydroformylation of methyl methacrylate is highly dependent on the catalyst used and reaction temperature, and can provide 2-formyl-2-methylpropanoate (**55**) or 3-formyl-2-methylpropanoate (**56**) selectively (Eq. 26).^{251,325}

Vinyl ethers. Hydroformylation of vinyl ethers provides efficient routes to alkoxy aldehydes.³²⁶⁻³³¹ The reaction of terminal vinyl ethers gives mixtures of regioisomers, the branched aldehyde being the major product (Eq. 27).³³² The re-

gioselectivity depends on the substituent R, e.g., methyl vinyl ether gives methoxypropanal with a b/l ratio of 54/46, while a b/l ratio of 95/5 is observed for phenyl vinyl ether.³³²

Hydroformylation of 2,3- or 2,5-dihydrofuran gives a mixture of 2- and 3-formyltetrahydrofuran (**58**, **59**), since isomerization of the double bond appears to take place extensively (Eq. 28).³³³ Under optimized conditions using $\text{Rh}_2[\mu-$

$\text{S}(\text{CH}_2)_3\text{NMe}_2]_2(\text{COD})_2$ (**57**) and 10 equivalents of PPh_3 or $\text{P}(\text{OMe})_3$, 3-formyltetrahydrofuran (**59**) is obtained from 2,5-dihydrofuran with 99% regioselectivity.^{333,334} In contrast, reactions of dihydro-2*H*-pyrans with the same catalyst system do not occur selectively.³³³ However, this catalyst system has been successfully applied to achieve regio- and stereoselective hydroformylation of glucal derivatives (Eq. 29).³³⁵ Alkenyl acetals can be employed as substrates for hydroformylation, giving the corresponding monoacetals of alkanedials.³³⁶⁻³⁴⁰

Halogenated alkenes. Hydroformylation of vinyl chloride gives 2-chloropropanal, a versatile intermediate for agrochemical and pharmaceutical agents.³⁴¹⁻³⁵³ The hydroformylation of 3,3,3-trifluoropropene (**60**) catalyzed by $\text{Co}_2(\text{CO})_8$ gives 3-trifluoromethylpropanal (**61**) with high linear selectivity ($l/b = 93/7$), while reactions catalyzed by rhodium complexes afford 2-trifluoromethylpropanal (**62**) with excellent branched selectivity ($l/b = 5/95 - 3/97$) (Eq. 30).^{354,355} These trifluoromethylpropanals are further transformed to *N*-acetyltrifluoronorvaline (**63**) and *N*-acetyltrifluorovaline (**64**) through ami-

dicarbonylation in high yields (Eq. 30).³⁵⁶ The rhodium complex-catalyzed hydroformylation of other fluoroolefins, $R_f\text{CH}=\text{CH}_2$ ($R_f = \text{F}$, perfluoroalkyl, C_6F_5), also gives the corresponding branched aldehydes with 92–100% selectivities.^{355,357,358} The hydroformylation-amidocarbonylation of pentafluorostyrene (**65**) catalyzed by $\text{Rh}_4(\text{CO})_{12}/\text{Co}_2(\text{CO})_8$ affords 3-methylpentafluorophenylalanine (**66**) in one step with 98% regioselectivity; **66** is readily cyclized to tetrafluoroindole **67** (Eq. 31).³⁵⁹

Alkenylamines and alkenylamides. Hydroformylations of olefins bearing amine or amide groups often give nitrogen heterocycles through condensation of the resulting aldehyde and the amine or amide moiety.^{248,278,313,360–364} The reaction of *N*-allyl-*N*-(2-phenylethyl)amine (**68**) catalyzed by a Rh/Ru mixed system gives pyrrolidinone **69** exclusively in high yield (Eq. 32).³⁶⁰

Amine-directed hydroformylation of 5-benzylamino-1-pentene (**70**) catalyzed by $\text{RhH}(\text{CO})(\text{PPh}_3)_3$ affords methylpiperidine **71** with 95% regioselectivity via the branched aldehyde intermediate (Eq. 33).³⁶² In the same manner, reaction of

4-pentenamide **73** catalyzed by $\text{RhCl}(\text{PPh}_3)_3$, $\text{RhCl}(\text{CO})(\text{PPh}_3)_2$, $\text{RhH}(\text{CO})(\text{PPh}_3)_3$ or $\text{Rh}_4(\text{CO})_{12}$ leads to the exclusive formation of methyl-dihydropyridone **74** in excellent yield (Eq. 34).³⁶³

Hydroformylation of 2-aminostyrene (**75**) catalyzed by the diphosphite-Rh complex **30** gives 3-methylindole (**76**) in quantitative yield (Eq. 35).²⁴⁸ In a simi-

lar manner, reaction of 2-amino-1-(1-hydroxy-2-propenyl)benzene (**77**) affords a 91:9 mixture of didehydrobenzoazepine **78** and quinoline **79** in high yield (Eq. 36).^{313,361} A tricyclic benzimidazole **81** is formed in one step in high yield from 1-alkenylamino-2-aminobenzene **80** (Eq. 37).³⁶⁴

Miscellaneous. Substrates containing phosphorus, sulfur and silicon functional groups, e.g., $-\text{P}(\text{O})\text{R}_2$,^{288,365} $-\text{P}(\text{O})(\text{OR}^1)\text{R}^2$,³⁶⁶ $-\text{SR}$,³⁶⁷⁻³⁷⁰ $-\text{S}(\text{O})\text{R}$,^{369,371} $-\text{SO}_2\text{R}$,^{369,371} $-\text{CH}(\text{SR})_2$,^{135,367,372-374} $-\text{SiR}_3$,^{118,315,368,375,376} $-\text{OSiR}_3$,¹³⁵ and $-\text{Si}(\text{OR})_3$,^{375,377} undergo hydroformylation with rhodium and cobalt catalysts to give the corresponding aldehydes. Phosphine and phosphite moieties possess strong directing effects as described above (see Eqs. 16, 17). Although hydroformylation of alkynes gives the corresponding conjugated aldehydes in moderate yield accompanied by saturated aldehydes (Eq. 38),^{368,378,379} reactions of functionalized alkynes

often give carbocyclic or heterocyclic compounds.³⁸⁰⁻³⁸³ Propargylamines form pyrroles, usually accompanied by lactone byproducts arising from deamination, as well as hydrogenated byproducts (Eq. 39).^{380,384} Alkenes bearing organometal-

lic moieties such as vinylferrocene,^{385,386} vinylbenzene- $\text{Cr}(\text{CO})_3$,³⁸⁷ and indene- $\text{Cr}(\text{CO})_3$ ^{387,388} are good substrates for hydroformylation. The benzene-chromium moiety has a strong directing effect to form the branched aldehyde in excellent regioselectivity (Eq. 40).³⁸⁷ Hydroformylation of oxiranes gives 1,3-diols or

3-hydroxyaldehydes.³⁸⁹⁻³⁹³ The hydroformylation of polymers bearing unsaturated tethers or pendant groups is useful for the production of polymers with formylalkyl groups.³⁹⁴⁻³⁹⁷

Asymmetric Hydroformylation

Asymmetric hydroformylation of prochiral olefins has been investigated both for the elucidation of reaction mechanism and for development of a potentially useful method for asymmetric organic synthesis. Rhodium and platinum complexes have been extensively studied, and cobalt complexes to a lesser extent. A variety of enantiopure or enantiomerically enriched phosphines, diphosphines, phosphites, diphosphites, phosphine-phosphites, thiols, dithiols, *P,N*-ligands, and *P,S*-ligands have been developed as chiral modifiers of rhodium and platinum catalysts.^{33,398-403}

In spite of extensive studies on the asymmetric hydroformylation of olefins using chiral rhodium and platinum complexes, enantioselectivities had not exceeded 60% ee until the reaction of styrene catalyzed by $\text{PtCl}_2(\text{DBP-DIOP})/\text{SnCl}_2$ (**82**) was reported to attain 95% ee in 1982.⁴⁰⁴ Although the value was corrected to 73% ee in 1983,⁴⁰⁵ this result spurred further studies of the reaction (Eq. 41) in connection with possible commercial synthesis of anti-inflammatory drugs such as (*S*)-ibuprofen and (*S*)-naproxen. The catalyst $\text{PtCl}_2(\text{BPPM})/\text{SnCl}_2$ (**83**) is useful for asymmetric hydroformylation of styrene and its derivatives, yielding the branched aldehyde **86**.⁴⁰⁶ For example, this catalyst gave the corresponding aldehyde in 70–80% ee for styrene, 80% ee for *p*-isobutylstyrene, and 81% ee for 2-ethenyl-6-methoxynaphthalene. Although the branched/linear ratios were low (0.5–0.7), the enantioselectivities achieved were considerably higher than those realized with any other chiral catalyst system at that time. A chiral platinum catalyst, $\text{PtCl}_2(\text{BCO-DBP})/\text{SnCl}_2$ (**84**), also achieved 86% ee for the reaction of styrene with much better branched/linear ratio (4:1).⁴⁰⁷ Higher enantioselectivity (91% ee) for the hydroformylation of styrene was achieved with the platinum-bis(phosphite) **85**-Sn system, although regioselectivities did not exceed a branched/linear ratio of 60/40.⁴⁰⁸

One of the difficulties in achieving high enantioselectivity in asymmetric hydroformylation is the propensity of chiral aldehydes **86** to racemize under the reaction conditions. Accordingly, if the chiral aldehyde can be converted to a less labile derivative in situ, higher enantioselectivity might be anticipated. In fact, when asymmetric hydroformylation of styrene and its derivatives catalyzed by $\text{PtCl}_2(\text{BPPM})/\text{SnCl}_2$ is carried out in triethyl orthoformate, the diethyl acetals of chiral aldehydes **87** are obtained with >96% ee (Eq. 42).^{406,409,410} It is reported

that a chiral platinum-phosphine catalyst anchored on cross-linked beads **88** bearing BPPM as the pendant group gives virtually the same enantioselectivity (up to

>98% ee at 22% conversion) as that attained by the homogeneous catalyst system in the reaction of styrene.^{406,410-412} Hydroformylations in triethyl orthoformate are slow, but enantioselectivities are excellent. Because of the low reaction rate and low regioselectivity, this protocol does not appear to be practical.

A breakthrough in asymmetric hydroformylation has been realized by using rhodium complexes with a novel phosphine-phosphite ligand, (*R,S*)-BINAPHOS (**89**).³⁴ The $\text{Rh}(\text{acac})(\text{CO})_2\text{-BINAPHOS}$ (**89**) catalyst can achieve excellent enantioselectivities (85–95% ee) in the hydroformylations of a variety of prochiral olefins such as vinyl acetate, *N*-vinylphthalimide, styrene and its derivatives, and 1,3-dienes^{34,36,413} with high branched/linear ratios (84/16–92/8) and good reaction rates at 60–80° (Eq. 43). A similar phosphine-phosphite ligand, (*S,R*)-BIPHENPHOS (**90**), has also been developed, and its Rh complex can achieve the same high level of enantioselectivity as (*R,S*)-BINAPHOS.^{414,415}

R = AcO, phthalimido, phenyl, tolyl, 4-isobutylphenyl

A rhodium complex with a polymer-supported (*R,S*)-BINAPHOS (**91**) has achieved high enantioselectivities similar to those obtained in the homogeneous system, showing promise for the development of practical heterogenized reusable chiral catalysts (Eq. 44).⁴¹⁶

91

The Rh complex with the chiral diphosphite ligand **92** derived from (*R,R*)-pentane-2,4-diol has shown enantioselectivity up to 90% ee with 98% branched

aldehyde selectivity.^{38,417} Phosphine-phosphinite ligands such as **93** show high asymmetric induction and high regioselectivity in the Rh-catalyzed hydroformylation of 4-vinyl- β -lactams.⁴¹⁸

Chiral aldehydes with high enantiopurity obtained through asymmetric hydroformylation serve as useful intermediates for pharmaceutical drugs.⁴¹⁹ For example, (*S*)-2-arylpropanals (**86**) can be oxidized to the corresponding (*S*)-2-arylpropanoic acids **94**, which are anti-inflammatory drugs such as (*S*)-ibuprofen (**94a**: Ar = 4-isobutylphenyl), (*S*)-naproxen (**94b**: Ar = 6-methoxynaphthyl), and (*S*)-suprofen (**94c**: Ar = 4-(2-thienylcarbonyl)phenyl) (Eq. 45).⁴⁰⁶

COMPARISON WITH OTHER METHODS

Hydroformylation is a useful catalytic method for the synthesis of aldehydes from alkenes and alkynes. There are no other methods that compete directly with hydroformylation for the synthesis of alkyl aldehydes. However, when the desired compounds are carboxylic acids or esters, and aldehydes are used as their

intermediates, there are other methods that can give the desired compounds directly from alkenes, i.e., hydrocarbohydroxylation and hydrocarbalkoxylation catalyzed by transition metal complexes.^{4,420} The hydroformylation of alkynes does not cleanly afford conjugated alkenyl aldehydes mainly because of extensive hydrogenation associated with the process. For the synthesis of conjugated alkenyl aldehydes, the formylation of aryl halides, alkenyl iodides, alkenyl triflates, and allylic halides is a convenient method. The silylformylation of alkynes also provides an efficient method, although a silyl group is incorporated in the product along with a formyl group.

Hydrocarbohydroxylation and Hydrocarbalkoxylation

The hydrocarbohydroxylation of 1-alkenes is promoted by nickel, cobalt, platinum, and palladium catalysts to give linear and branched alkanolic acids in differing ratios (Eq. 46).^{4,420,421} Nickel catalysts, e.g., $\text{Ni}(\text{CO})_4$, NiCl_2 , NiI_2 and

Raney Ni, favor formation of the branched product, while $\text{Co}_2(\text{CO})_8$ /pyridine, $\text{H}_2\text{PtCl}_6/\text{SnCl}_2$, and $\text{PdCl}_2(\text{PPh}_3)_2/\text{HCl}$ catalyst systems give the linear carboxylic acid as the predominant product.⁴²⁰ The nickel and cobalt catalysts usually require high temperature (150–250°) and high carbon monoxide pressure (150–250 atm). Although platinum and palladium catalysts can promote the reaction at lower temperatures, often an extremely high pressure (700–800 atm) is required.^{420,421} Although the platinum catalyst $\text{H}_2\text{PtCl}_6/\text{SnCl}_2$ can only promote the reaction of 1-alkenes,⁴²² other catalysts can be used for internal olefins, cycloalkenes, and vinylidenealkanes.⁴²¹

The reaction of 1,3-butadiene catalyzed by $\text{PdCl}_2(\text{PPh}_3)_2/\text{HCl}$ (120–140°, 700 atm)⁴²¹ and $\text{Co}_2(\text{CO})_8$ /pyridine (160°, 250 atm) forms 3-buten-1-oic acid in high yield, and this can be further transformed to adipic acid in a reasonable yield using the cobalt catalyst at higher temperature (210°) (Eq. 47).⁴²⁰

A palladium complex generated in situ by mixing $\text{Pd}(\text{OAc})_2$ with DPPB and HCO_2H (2 equivalents) is an excellent catalyst system for the hydrocarbohydroxylation of a variety of terminal olefins, which gives linear acids with excellent regioselectivity (74–100%) at 150° and 6.8 atm of carbon monoxide.⁴²³ For example, the reactions of 2,4,6-trimethylstyrene, 3,3-dimethyl-1-butene, 2,2-

dimethyl-4-pentanal, and 4-vinylcyclohexene (Eq. 48) give the corresponding linear acids as the only products in high yields (75–98%).

In a manner similar manner, the hydrocarbalkoxylation (commonly called hydroesterification) of alkenes in the presence of alcohols can be effected by the nickel, cobalt, platinum, and palladium catalysts described above (Eq. 49).^{4,420,421}

The reaction of 1,3-butadiene catalyzed by PdCl_2 gives an alkyl 3-pentenoate (Eq. 50), whereas the $\text{Pd(OAc)}_2(\text{PPh}_3)_2$ -catalyzed reaction yields an alkyl 3,8-nonadienonate via a dimerization-carbonylation process (Eq. 51).^{4,424}

An (*R,S*)-naproxen ester **96** is obtained through regioselective hydrocarbalkoxylation of 6-methoxy-2-naphthylethene (**95**) catalyzed by $\text{PdCl}_2[\text{P}(c\text{-C}_6\text{H}_{11})\text{Ph}_2]_2$ with 100% regioselectivity in 95% yield (Eq. 52).⁴²⁵

(Eq. 52)

The hydrocarbalkoxylation of trimethylvinylsilane catalyzed by $\text{PdCl}_2(\text{PPh}_3)_2$ gives 3-(trimethylsilyl)propanoate with 95–100% selectivity, while the $\text{Co}_2(\text{CO})_8$ -catalyzed reaction affords 2-(trimethylsilyl)propanoate with 91–100% selectivity (Eqs. 53, 54).⁴²⁶ A platinum complex, $\text{PtCl}_2(\text{AsPh}_3)_2$, can also give the linear product with 100% selectivity. The reactions of other vinylsilanes bearing different

substituents on silicon show the regioselectivity switching between the palladium and the cobalt catalysts as well. Highly regioselective hydrocarbohydroxylation of trimethylvinylsilane can be effected by $\text{PdCl}_2(\text{PPh}_3)_2$, giving 3-(trimethylsilyl)propanoic acid in 95% yield.⁴²⁶

The hydrocarbohydroxylation of pentafluorostyrene catalyzed by $\text{PdCl}_2(\text{DPPB})$ in $\text{AcOH}/\text{H}_2\text{O}$ gives 3-(pentafluorophenyl)propanoic acid with >99% selectivity, whereas the hydrocarbalkoxylation of pentafluorostyrene catalyzed by $\text{PdCl}_2(\text{PPh}_3)_2$ in $\text{MeOH}/\text{benzene}$ yields methyl 2-(pentafluorophenyl)propanoate with 95% selectivity (Eqs. 55, 56).⁴²⁷

The hydrocarbohydroxylation of phenylacetylene catalyzed by $\text{Ni}(\text{CN})_2$ under mild phase transfer conditions using cetyltrimethylammonium bromide (CTAB) gives atropic acids in excellent yield (Eq. 57).⁴²⁸

Asymmetric Hydrocarbohydroxylation and Hydrocarbalkoxylation

Asymmetric hydrocarbalkoxylation of alkenes has been studied since early 1970s, but the number of papers published on this subject is much less than that on asymmetric hydroformylation. This is mainly due to the fact that these reactions catalyzed by palladium complexes with chiral phosphine ligands usually require a very high pressure of carbon monoxide, which is rather difficult for academic laboratories to provide. However, new processes that do not require high pressure have been developed, which make these potentially useful reactions in organic synthesis more attractive. Apparently, it has been difficult to achieve high enantioselectivity in these reactions.¹¹¹ For example, until 1997 the best

enantioselectivity attained in asymmetric hydrocarbalkoxylation was 69% ee (at 8% conversion) in the reaction of 2-phenylpropene with *tert*-butyl alcohol catalyzed by a palladium complex with DBP-DIOP (**82**) (100° and 220–240 atm of CO), giving *tert*-butyl 3-phenylbutanoate.⁴²⁹ A closely related catalyst system, PdCl₂/DIOP, catalyzed the reaction of methyl methacrylate (100° and 370–400 atm of CO) to give methylsuccinic acid monomethyl ester with 49% ee.^{430,431} Although an improved process for asymmetric hydrocarbalkoxylation under mild conditions (50° and 1 atm of CO) was developed in 1982 using Pd(*dba*)₂, neomenthylidiphenylphosphine, and trifluoroacetic acid in methanol,⁴³² there appears to have been no further development of this catalyst system. However, quite recently a similar system, Pd(OAc)₂/BPPFA/*p*-toluenesulfonic acid, has achieved 86% ee in the reaction of styrene.⁴³³ Very recently, a PdCl₂/CuCl₂/diphosphine catalyst system with a unique chiral diphosphine, 1,4:3,6-dianhydro-2,5-dideoxy-2,5-bis(diphenylphosphino)-L-idiol, was reported to achieve 99% ee,⁴³⁴ which is very encouraging and warrants further investigation.

For asymmetric hydrocarbohydroxylation, an efficient catalyst system consisting of PdCl₂, CuCl₂, and (*R*)-1,1'-binaphthyl-2,2'-diyl hydrogen phosphate (BNPPA) was introduced in 1990, and can promote the reaction at ambient temperature and pressure.⁴³⁵ The reactions of 4-isobutylstyrene and 6-methoxy-2-naphthylethene (**95**) promoted by the PdCl₂/CuCl₂/*(R)*-(-)-BNPPA catalyst give (*S*)-ibuprofen (**94a**) with 83–84% ee and (*S*)-naproxen (**94b**) with 91% ee, respectively (Eq. 58).⁴³⁶ Although 10–25 mol% of the chiral palladium catalyst is required to promote the reaction efficiently, this process has high potential because of mild reaction conditions and high enantioselectivity achieved.

Formylation of Halides and Triflates⁴³⁷

Catalytic formylation of aryl, heteroaryl, and vinylic halides in the presence of an amine, carbon monoxide, and hydrogen using a palladium complex such as PdCl₂(PPh₃)₂ provides a convenient route to conjugated aldehydes in good to excellent yields (Eq. 59).⁴³⁸ The use of iodo substrates secures excellent yields.

Allylic halides can be used as the substrates, but the yields of the resulting β,γ -unsaturated aldehydes are modest (38–42%).⁴³⁹ When 1,3-bis(diisopropylphosphino)propane (DIPPP) is used as the ligand for palladium catalyst, and sodium

formate as the hydrogen source, aryl chlorides are converted to the corresponding aldehydes in excellent yield under mild conditions (Eq. 60).

The use of a silicon hydride or a tin hydride in place of molecular hydrogen allows the formylation of aryl halides to proceed under much milder conditions. The reactions of aryl and benzylic bromides/iodides catalyzed by $\text{Pd}(\text{PPh}_3)_3$ in the presence of poly(methylhydrosiloxane) (PHMS) at 80° and 3 atm of carbon monoxide afford the corresponding aldehydes in 48–96% yields.⁴⁴⁰ When 1-bromo-4-iodobenzene is used as the substrate, 4-bromobenzaldehyde is formed exclusively in 95% yield (Eq. 61).⁴⁴⁰

Almost the same procedure except for using tributyltin hydride as the hydrogen source provides a convenient and versatile method for the synthesis of aldehydes from aryl iodides/bromides, benzylic and vinylic halides, vinylic triflates, and allylic halides.⁴⁴¹ This protocol allows the reactions to proceed at ca. 50° and 1–3 atm of carbon monoxide, and a variety of functional groups can be tolerated (Eqs. 62–64).⁴⁴¹

Primary and secondary alkyl iodides can be formylated with the platinum complex $\text{PtCl}_2(\text{PPh}_3)_2$, instead of palladium complexes as the catalyst in good to high yield at 120° and 100 atm of carbon monoxide and hydrogen (1:1) in the presence of potassium carbonate (Eq. 65).⁴⁴²

Silylformylation of Alkynes

Silylformylation of 1-alkynes gives 1-silyl-2-formyl-1-alkenes with excellent regio- and stereoselectivity (Eq. 66).⁴⁴³⁻⁴⁴⁵ This reaction is catalyzed by rho-

dium or rhodium-cobalt complexes such as $\text{Rh}_4(\text{CO})_{12}$,⁴⁴³⁻⁴⁴⁵ $\text{Rh}_2\text{Co}_2(\text{CO})_{12}$,^{444,445} $\text{Rh}(\text{CN-Bu-}t)_4\text{Co}(\text{CO})_4$,⁴⁴⁵ $\text{Rh}(\text{acac})(\text{CO})_2$,⁴⁴⁵ $\text{Rh}_2(\text{pfb})_4$ (pfb = perfluorobutyrate),⁴⁴⁶ and $(\eta^6\text{-C}_6\text{H}_5\text{BPh}_3)\text{Rh}(\text{COD})$ (**29**)⁴⁴⁷.

When internal alkynes are used, a mixture of regioisomers is formed.⁴⁴³ A mixture of *Z* and *E* isomers in varying ratios is obtained depending on the catalyst species and reaction conditions.^{443,446} Functional groups such as olefin, hydroxy, ester, ether, amide and nitrile are tolerated.^{443,445-447} The reaction of 5-ethynylpiperidin-2-one (**96**) was successfully applied to the synthesis of isoretronecanol (**98**) (Eq. 67).^{445,448}

Although the reaction of 1-alkynes always affords 2-formyl products as shown in Eq. 66, this regiochemistry can be completely reversed using intramolecular silylformylation via *exo-dig* cyclization of alkynylsilanes⁴⁴⁹ and alkynylloxysilanes⁴⁵⁰ (Eqs. 68-70).

$R^1 = \text{H, alkyl, Ph}; R^2 = \text{H, Me}; R^3, R^4 = \text{Me, Ph}; n = 1, 2$

EXPERIMENTAL CONDITIONS

Hydroformylation is usually carried out under catalytic conditions. The alkene, catalyzed by metal complexes under carbon monoxide and hydrogen in hydrocarbon, alkyl halide or ether solvent, generates the hydroformylation product. Rhodium catalysts are preferred for laboratory syntheses because of their higher activity and selectivity. Improvements in regioselectivity and yields have been found when the reaction is carried out in the presence of added donor ligands such as trialkylphosphines, or under UV irradiation. Catalysts supported on polymers have been used for easy separation of product and reuse of catalysts.

Carbon monoxide. Carbon monoxide is a colorless, odorless gas, liquefying at -191.5° . It is readily available, at pressures of up to about 100 bar, in a variety of cylinder sizes, so that experiments can be run at 80 bar without a compressor. The acute toxicity of carbon monoxide reflects its high affinity for hemoglobin. It is stated⁴⁵¹ that 400–500 ppm of carbon monoxide in air can be breathed for an hour without appreciable effect, while levels above 1000 ppm are dangerous, and at more than 4000 ppm it causes death within an hour. The previously cited reference gives a Threshold Limit Value of 50 ppm. Carbon monoxide must always be used in an efficient fume cupboard, keeping emissions into the laboratory atmo-

sphere to an absolute minimum. If carbon monoxide is in routine use it is recommended that an electronic detection system be installed to provide continuous monitoring of the laboratory atmosphere. For atmospheric pressure reactions, conventional rubber tubing or clear PVC tubing can be employed in laboratories, with appropriate securing clips, for delivering carbon monoxide to the reaction system. Higher pressures require the use of stainless steel tubing and couplings.

EXPERIMENTAL PROCEDURES

Cyclohexanecarboxaldehyde [Hydroformylation of an Alkene under Classical Homogeneous Conditions].⁴⁵² To a stainless steel 0.5 L pressure vessel equipped with a 450-atm manometer and a temperature recorder was added 0.2 g (0.8 mmol) of rhodium(III) oxide. The vessel was then sealed and evacuated to 0.1 mm Hg pressure. A solution of 82 g (1 mol) of cyclohexene in 140 mL of anhydrous benzene was introduced by suction into the vessel. The vessel was placed in a heatable shaking device and pressured to 75 atm with carbon monoxide, then the total pressure was increased to 150 atm with hydrogen. Shaking was begun and the vessel was heated to an internal temperature of 100°. When the internal temperature reached 100°, the pressure began to fall. When the pressure had fallen to 60 atm, rocking was stopped and carbon monoxide was introduced to 105 atm and then hydrogen to 150 atm. Rocking was started again, and the process was continued until no appreciable pressure decrease occurred. Approximately two hours was required, and the pressure decrease corresponded to the consumption of 2 moles of gas. The vessel was rapidly cooled to room temperature and the residual gas was carefully vented. The vessel was opened, and the slightly yellow reaction mixture was transferred immediately to a 2-L round-bottomed flask containing a freshly prepared solution of 200 g of sodium hydrogen sulfite in 400 mL of water. The flask was fitted with a stopper and was occasionally shaken at room temperature for a period of 3 hours. The resulting precipitate was collected by suction filtration on a sintered-glass funnel and washed with 500 mL of ether. After drying in air, the bisulfite derivative was transferred to a 2-L distillation flask containing 1 L of 20% aqueous potassium carbonate. The resulting mixture was distilled, and the azeotropic mixture of water and aldehyde (bp 94–95°) was collected under nitrogen. The aldehyde was separated from the lower aqueous layer as a colorless liquid and dried over 10 g of anhydrous sodium sulfate. The drying agent was removed by filtration, and the product was distilled under reduced pressure using a Claisen distillation apparatus to give 92–94 g (82–84%) of cyclohexanecarboxaldehyde, bp 52–53° (18 mm), n_D^{25} 1.4484. A purity of about 98% was established by GC analysis.

(7,7-Dimethylnorborn-2*R*-yl)-acetaldehyde [Hydroformylation of an Alkene under Homogeneous Conditions].⁴⁵³ A 200 mL autoclave was charged with 5.0 g (37 mmol) of (+)- α -fenchene, 45.3 mg (0.18 mmol) of the dimer of rhodium(I) chloride-1,5-cyclooctadiene, 95 mg (0.36 mmol) of triphenylphosphine, 0.5 mL of triethylamine and 25 mL of benzene, and the reaction was carried out at 90° for 16 hours under a synthesis gas pressure of 80 kg/cm² (CO pressure 40 kg/cm²; H₂ pressure 40 kg/cm²). The solvent was evaporated, and the residue was fractionally distilled under reduced pressure to give 5.7 g (93.4%) of the product. The *exo/endo* ratio of the product was determined to be 85:15 by ¹H NMR; bp 54–55° (0.2 mm); ¹H NMR (CDCl₃) δ : *exo form* 9.71 (t, *J* = 7.9 Hz, 1 H, CHO), 2.60 (ddd, *J* = 2.1, 5.9, 9.6 Hz, 2 H, CH₂CHO), 1.08 (s, 3 H, CH₃), 0.97 (s, 3 H, CH₃); *endo form* 9.76 (t, *J* = 7.9 Hz, 1 H, CHO), 1.08 (s, 3 H, CH₃), 1.02 (s, 3 H, CH₃); MS (*m/z*): 166 (M⁺), 151, 133, 123, 122 (base), 107, 95, 81, 79, 69, 67, 55, 41. Anal. Calcd for C₁₁H₁₈O: C, 79.52; H, 10.84. Found: C, 79.40; H, 10.86.

6-Oxoheptanal.¹³⁵ Into a Fisher-Porter bottle, fitted with a pressure coupling closure complete with gas inlet, pressure gauge, and pressure release valve, was added (acetylacetonato)dicarbonylrhodium (28 mg, 0.109 mmol, 0.54 mol%), BIPHEPHOS (**25**) (320 mg, 0.408 mmol), THF (36 mL), and 5-hexen-2-one (2.32 mL, 20 mmol). The reaction vessel was degassed three times and purged with CO/H₂ (1:1 mixture) for several minutes. The reaction vessel was pressurized at room temperature to 60 psi with CO/H₂ (1:1 mixture) and then heated at 60° for 18 hours. After cooling to room temperature, the pressure was released and the solution concentrated. The resulting oil was purified by Kugelrohr distillation to give a colorless oil, 6-oxoheptanal (2.21 g, 86% yield).

(*S*)-2-(6-Methoxy-2-naphthyl)propanal [Asymmetric Hydroformylation of a Vinylarene under Homogeneous Conditions].⁴⁰⁶ A deoxygenated so-

lution of 1.0 g (5.4 mmol) of 6-methoxy-2-naphthylethene in 15 mL of benzene was charged into a 125-mL Parr Monel bomb with 16 mg (0.02 mmol) of $[(\text{-})\text{-BPPM}]\text{PtCl}_2$ and 11 mg (0.05 mmol) of stannous chloride dihydrate. The bomb was sealed, pressurized to 2700 psi, and heated with stirring at 60° for 9 hours. At the end of the reaction, the bomb was quenched in a dry ice bath, the pressure was vented, and the mixture was eluted with benzene through an MPLC apparatus to afford 350 mg (30.1%) of the branched aldehyde (b/n = 0.7): mp 145° ; 81% ee (determined by $^1\text{H NMR}$ using $\text{Eu}(\text{hfc})_3$ as chiral shift reagent); $^1\text{H NMR}$ δ 9.7 (d, $J = 4.1$ Hz, 1 H), 7.7–7.1 (m, 6 H), 3.9 (s, 3 H), 3.7 (dq, $J = 6.3, 4.1$ Hz, 1 H), 1.6 (d, $J = 6.3$ Hz, 3 H). Anal. Calcd for $\text{C}_{14}\text{H}_{14}\text{O}_2$: C, 78.50; H, 6.54. Found: C, 78.38; H, 6.59.

(S)-2-(4-Isobutylphenyl)propanal [Asymmetric Hydroformylation of a Vinylarene under Homogeneous Conditions].³⁸ A catalyst solution was prepared consisting of 0.011 g of (acetylacetonato)dicarbonylrhodium (1500 ppm rhodium), 0.765 g of (isoBHA-P)₂-(2R,4R)-pentandiol (**92**) (4:1 ligand to rhodium ratio), 5 g of 4-isobutylstyrene, and 24.5 g of acetone. This solution was charged to a 100 mL reactor and charged to a pressure of 67 psi with hydrogen gas and 200 psi with carbon monoxide (at ambient temperature). The rate of the reaction was determined by monitoring the drop in pressure as syngas was consumed. The reaction rate was approximately 0.1 g-mole/L/h. When the rate had slowed because of consumption of starting material, the reaction mixture was removed from the reactor under a nitrogen atmosphere. A portion of the reaction mixture was analyzed by GC to determine product composition. An isomer ratio of 66:1 [2-(4-isobutylphenyl)propanal: 3-(4-isobutylphenyl)propanal] was observed.

Determination of enantiomeric purity. Three mL of the solution was diluted in 50 mL of acetone and treated with 0.3 g of potassium permanganate and 0.32 g magnesium sulfate to effect oxidation of the product aldehydes to their respective acids. The mixture was stirred at room temperature for 30 minutes after which time the solvent was removed under reduced pressure. The residue was extracted three times with 50 mL of hot water. The three aqueous solutions were then combined, filtered, and washed with 50 mL of chloroform. The aqueous layer was acidified with hydrochloric acid to a pH of 2 and then extracted with 50 mL of chloroform. The chloroform was removed in vacuo and the resulting residue dissolved in 0.5 mL of toluene. This solution was analyzed by GC on a chiral β -cyclodextrin column which separated the two enantiomers of the resulting 2-arylpropanoic acid. This analysis indicated a 91:9 ratio of the *S* and *R* enantiomers for an ee of 82%.

(S)-2-Acetoxypropanal [Asymmetric Hydroformylation of a Vinyl Ester under Homogeneous Conditions].³⁴ A solution of vinyl acetate (532.3 mg, 6.19 mmol), Rh(acac)(CO)₂ (4.0 mg, 1.55 × 10⁻² mmol), and (R,S)-BINAPHOS (**89**) (17.7 mg, 3.34 × 10⁻² mmol) in benzene (10 mL) placed in a Schlenk tube was degassed by freeze-thaw cycles. It was then transferred into a 50 mL autoclave, and the mixture was stirred at 60° for 36 hours under hydrogen and carbon monoxide pressure (1:1 ratio, total 100 atm). ¹H NMR analysis of the reaction mixture showed that the conversion was >99% and the branched and normal aldehydes (2-acetoxypropanal and 3-acetoxypropanal) were formed in 86:14 ratio. The enantiomeric excess of (S)-2-acetoxypropanal (92%) was determined by GC using a chiral capillary column.

exo-Norbornanecarboxaldehyde [Asymmetric Hydroformylation of an Alkene using a Cross-Linked Polymer-Supported Catalyst under Heterogeneous Conditions].⁴¹¹ *Preparation of the Polymer-Supported Ligand.* A solution of 500 mg of poly(vinylpyrrolidone) (*M_r* 40000) in 60 mL of water was degassed by two freeze-pump-thaw cycles, transferred to a 250 mL Morton creased flask containing a variable speed stirrer, and heated to 65° under argon. A mixture of 441.5 mg (0.77 mmol) of (4*R*,5*R*)-2-(*p*-styryl)-4,5-bis[(dibenzophospholy)methyl]-1,3-dioxolane, 648.2 mg (6.22 mmol) of styrene, 101.1 mg (0.77 mmol) of divinylbenzene, 50 mg of azobis(isobutyronitrile), and 2 mL of toluene was deoxygenated and added to the flask. The suspension was stirred for 20 hours, cooled, treated with 30 mL of methanol, and stirred for 30 minutes. The beads were filtered in a glove bag, washed with 50 mL of methanol, 50 mL of THF, 50 mL of benzene, and 50 mL of methanol, and dried under reduced pressure to afford 972.2 mg (80%) of 20–60 μm polymer beads: solid state ³¹P NMR (CP/MAS) δ -24.8 (broad signal with a shoulder at δ -18.8). Anal. Calcd: P, 4.01. Found: P, 4.18.

Preparation of the Polymer-Supported Catalyst. A solution of 0.12 mmol of bis(benzonitrile)dichloroplatinum(II) in 10 mL of benzene was added to a refluxing suspension of an amount of polymer beads containing 0.21 mmol of dibenzophosphole ligand in 5 mL of benzene. Reflux was continued for 40 hours under argon. The mixture was filtered in a glove bag, washed with 10 mL of dichloromethane and 10 mL of benzene, and dried under reduced pressure to afford the polymer-supported catalyst **I** in 98.6% yield: solid state ³¹P NMR (CP/MAS)

δ 2.0 (1J (Pt,P) = 3549 Hz), -24.7 (uncoordinated ligand). Anal. Calcd: Pt, 6.99. Found: Pt, 5.96.

A 125 mL Parr Monel bomb was charged with 0.02 mmol of the Pt polymer-supported catalyst **I** and 0.04 mmol of stannous chloride dihydrate. The bomb was brought into an argon-filled glove bag and charged with 8.7 mmol of norbornene dissolved in 3 mL of benzene. The bomb was sealed, pressurized, and vented three times with the synthesis gas mixture (1:1 CO:H₂) and then pressurized to 2700 psi and heated with stirring in an oil bath at 60° for 4 hours. At the end of the reaction, the bomb was opened in a glove bag. Catalyst **I** was recovered by filtration. The reaction mixture was analyzed by GC to determine the conversion (100%) and the aldehyde selectivity (87%). ¹H NMR of the mixture in the presence of Eu(hfc)₃ determined that the *exo*-norbornanecarboxaldehyde was obtained in 20% *ee*.

***n*-Heptanal and 2-Methylhexanal [Hydroformylation of an Alkene using Water-Soluble Complexes as Catalytic Precursors in a Two-Phase System].**²³ A mixture of 5.0 mL (40 mmol) of 1-hexene, 157.6 mg (0.1 mmol) of Rh₂(μ-S-*t*-Bu)₂(CO)₂(TPPTS)₂ and 568 mg (1.00 mmol) P(C₆H₄SO₃Na-*m*)₃ (TPPTS) in 30 mL of distilled and nitrogen-saturated water was introduced into the autoclave under vacuum. This was heated to 80°, with stirring; after 5 minutes the syngas (CO/H₂ = 1/1) was introduced at the working pressure (10 bar). After 18 hours, the solution was transferred from the autoclave into a Schlenk tube. The composition of the solution was determined by GC on an Intersmat I.G.C. 131 apparatus equipped with a 3 m × 0.125 in. diameter column of OV17 on chromosorb WHP. The reaction conversion was 100% and the aldehyde selectivity was 97% (*n*-heptanal/2-methylhexanal = 36).

***n*-Nonanal and 2-Methyloctanal [Fluorous Biphasic Hydroformylation of Alkene using Recycle Catalyst].**³¹ A mixture of 12.9 mg (0.05 mmol) Rh(acac)(CO)₂ in 35 mL of toluene and 2.14 g (2.00 mmol) P[(CH₂)₂(CF₂)₅CF₃]₃ in 35 mL of *c*-C₆F₁₁CF₃ was charged to a 300 mL autoclave under 5 atm CO/H₂ (1:1) and heated to 100°. A 75 mL pressure bomb was charged with 2.52 g (158 mmol) of 1-decene and attached to the autoclave. When the temperature in the autoclave reached 100°, the 1-decene was added by using 10 atm CO/H₂ (1:1) pressure, which was maintained during the reaction. After the reaction was complete, the reactor was cooled to room temperature. The autoclave was depressurized, and the two-phase system was separated in a separatory funnel under N₂.

The upper phase was recharged to the cleaned and catalytically inactive autoclave. A solution of 30 mL of 1-octene in 35 mL of toluene was added under 5 atm CO/H₂ (1:1) and heated to 100°. The pressure was increased to 10 atm CO/H₂ (1:1) and maintained for 24 hours. A GC analysis of the reaction mixture showed only trace amounts of conversion of 1-octene. In contrast, when the lower phase was charged to the autoclave, the hydroformylation of 1-octene proceeded to give 85% nonanals with *n/i* ratio of 2.9 and 8% octenes.

(*E,Z*)-3-Pentenal and 4-Pentenal [Hydroformylation of an Alkene Catalyzed by Mesitylene-Solvated Rhodium Atoms].²⁵⁴ Rhodium metal (82.8 mg, 0.8 mmol) was evaporated during 40 minutes and co-condensated with mesitylene (30 mL) at liquid-nitrogen temperature, using a glass metal-atom reactor. The matrix obtained was warmed to about -40° and the resulting brown solution siphoned under argon into a Schlenk tube and manipulated at -30° under argon.

To a portion of the above co-condensate containing 5.2 mg of rhodium were added 22 mg (0.05 mmol) of bis(diphenylphosphino)ethane and 32.5 mmol of 1,3-butadiene, and the solution so obtained was introduced by suction into an evacuated 80 mL stainless steel autoclave. When carbon monoxide was introduced to the desired pressure (60 atm), and the autoclave was rocked and heated to 80°, hydrogen gas was rapidly introduced to give a 1:1 gas composition (total pressure 120 atm). After 4 hours, the reaction mixture was analyzed by GC to determine the conversion (78%) and the aldehydes yield (76%). The ratio of 3-pentenal/4-pentenal was 96/4. (*E,Z*)-3-Pentenal (*E/Z* = 75/25): ¹H NMR δ 9.62 (t, *J* = 2 Hz, 1 H, CHO, *E*), 9.64 (t, *J* = 1.8 Hz, 1 H, CHO, *Z*); 5.38–5.90 (m, 2 H, CH = CH, *E* + *Z*); 3.12–3.20 (m, 2 H, CH₂, *Z*); 3.05–3.10 (m, 3 H, CH₂, *E*); 1.65–1.78 (m, 3 H, CH₃, *E*); 1.55–1.72 (m, 3 H, CH₃, *Z*); GC-MS (*m/e*) 84 (M⁺), 69, 55 (100). 4-Pentenal: ¹H NMR δ 9.75 (t, *J* = 1.5 Hz, 1 H, CHO); 5.04–5.07 (m, 1 H, -CH =); 4.94–5.02 (m, 2 H, = CH₂); 2.45–2.55 (m, 2 H, -CH₂-CHO); 2.35–2.40 (m, 2 H, -CH₂-CH₂); GC-MS (*m/e*) 84 (M⁺), 83, 55 (100), 41.

TABULAR SURVEY

As mentioned in the Introduction, the exhaustive review by Cornils on the hydroformylation reactions that appeared in 1980 compiled publications including patents and patent applications since its discovery in 1938 till sometime in 1978.³ Accordingly, the tabular survey in this chapter covers relevant examples abstracted from the literature from 1978 through 1998, and additional examples from crucial references up to November, 1999 have also been included. Because of the emphasis on the scope of the hydroformylation reactions as synthetic methods, patents and patent applications dealing with improvements of the well-

established industrial Oxo-Process are not included. The tabular survey starts from the hydroformylation of simple olefins, dienes, and polyenes in Tables I and II. Then, Tables III–IX are categorized according to different functional groups attached to olefinic substrates. Table X covers asymmetric hydroformylations of prochiral olefins, and Table XI summarizes the hydroformylation of acetylenes. Within each table the substrate compounds are listed according to increasing carbon numbers. Reaction conditions including solvent, temperature, pressure, and time are presented as they are available from the original references. The pressure unit differs from a paper to another paper, i.e., atmosphere (atm), bar, kg/cm², pounds per square inch (psi), and pascal (Pa). Although it might be confusing, the authors intentionally did not convert the reported pressures to a uniform pressure unit. The relations between different pressure units are as follows: 1 atm = 1.01325 bar = 1.03323 kg/cm² = 14.696 psi = 101.325 Pa. Yields and percent enantiomeric excess (% ee) are given in parentheses. A dash indicates that no yield is given in the reference.

The following abbreviations are used in the tables:

Ac	acetyl
acac	acetylacetonato
Bipy	2,2'-bipyridine
COD	cycloocta-1,5-diene
Cy	cyclohexyl
ee	enantiomeric excess
Pht	<i>o</i> -phthalyl
py	pyridine
Pz	pyrazolate
THF	tetrahydrofuran

The following catalysts and their abbreviations are listed in alphabetical order and are used throughout the Tabular Survey.

INTRODUCTION

In a previous chapter¹ we described the reactions of the Vilsmeier-Haack reagent with conjugated cyclic systems. In this chapter we extend the discussion to reactions between the Vilsmeier-Haack reagent (subsequently referred to as the Vilsmeier reagent for brevity) and any other compounds in which a carbon-carbon bond is formed. The discussion thus excludes reactions in which the Vilsmeier reagent acts as a chlorinating agent (for example in the preparation of acid chlorides), or in which it forms carbon-oxygen or carbon-nitrogen bonds, unless these are accompanied by formation of a carbon-carbon bond. For a discussion of the nature of the reagent and of the mechanism of the reaction, the earlier chapter should be consulted. There are also a number of reviews that deal at length with mechanisms of reactions involving the Vilsmeier reagent, notably those by Jutz² and Marson,³ and hence this chapter will concentrate on applications, with brief mention of mechanisms when necessary. Smaller reviews of the Vilsmeier reaction have been published by Balbi^{3a} and Seybold.^{3b}

The Vilsmeier reagent is regarded as the cation **1** where X is chlorine or dichlorophosphonyl. Wizinger pointed out⁴ that alkenes could react with the Vilsmeier reagent, but his only examples were styrenes (Eq. 1) where the intermediate carbocation has considerable stability.

(Eq. 1)

Hydrolysis gives the cinnamaldehyde. In principle, any alkene which is not too sterically hindered can undergo this reaction, but the Vilsmeier reagent has low reactivity as an electrophile, and in practice activation is often necessary. The addition depends on the HOMO of the alkene, and anything increasing the HOMO energy will aid reaction, as for example further conjugation (dienes, trienes, etc.) or the presence of an electron-donating substituent. Hence aldehydes and ketones are active in their enol forms, and enol ethers and enamines are good substrates. Indeed, all additions covered by this chapter can be regarded as alkene additions, even those on active methyl groups attached to electron-deficient rings. As with any reaction involving carbocation intermediates, rearrangements are possible; the initial products are sometimes enamines, and this can give rise to polysubstitution. In the section which follows the substrates are grouped into eleven major subsections; references to reviews of particular relevance will be found in the appropriate subsection.

SCOPE AND LIMITATIONS

Alkenes, Dienes, and Polyenes

Simple aliphatic alkenes are normally unreactive unless one end of the double bond has two alkyl substituents, as in methylenecyclohexane (**2**)⁵ (Eq. 2), or the

(Eq. 2)

more powerful stabilization of a conjugated aryl group (Eq. 1). The methylene group in compound **2** is still relatively unreactive, and the initial product, by

elimination of a proton, can form a more reactive substrate **3** so that further substitution takes place. Further reaction reaches an extreme in methylenebornane⁵ and isobutene⁶ which give, respectively, products with three and five amino-methylene substituents by successive shifts and secondary reactions. Camphene (**4**),^{7,5} where double bond migration cannot occur, reacts normally (Eq. 3).

The short lifetime of the intermediate carbocation is indicated by the formation of formyl derivatives from vinylcyclopropane (**5**)⁸ with no evidence of the opening of the cyclopropane ring that would normally be expected on formation of a carbocationic site α to the cyclopropane ring. The same paper illustrates an example of double bond migration prior to formylation: the major product from Vilsmeier reaction of the vinylcyclopropane **6** is the same as that from isomer **5** (Eq. 4); conversely, increasing the size of the substituent β to the cyclopropane ring can cause formylation of the thermodynamically unfavored isomer, as shown for compound **7** (Eq. 5).⁸

An indication of the relative activity of the aromatic ring vs. the alkene can be obtained from substituted stilbenes. Stilbene itself does not react, but 4-dimethylaminostilbene (**8**) forms aldehyde **9** (Eq. 6);⁹ at higher temperature or when a

large excess of Vilsmeier reagent is used, substitution also occurs on position 3 of the ring, giving compound **10**. These results are compared with Hückel calculations which show the reactivity as $3 = 5 > \alpha > 4$.¹⁰

Styrenes react with the Vilsmeier reagent to give cinnamaldehydes, often in excellent yields. In some cases, when the benzene ring is electron rich, the product at higher temperatures may be an indene, such as compound **11**,¹¹ formed by cyclization of the intermediate cation (Eq. 7). Polymerization of styrenes (and

dienes or polyenes) under electrophilic attack can be prevented by using a precursor alcohol, such as compound **12**, and relying on the known dehydrating ability of the Vilsmeier reagent to generate the alkene in situ (Eq. 8).¹²

Simple aliphatic dienes do not react satisfactorily to give dienals. A series of allylic alcohols has been treated with the Vilsmeier reagent to give benzene-1,3-dicarboxaldehydes, such as compound **13**, presumably via the diene and disubstitution of the terminal methyl group (Eq. 9).¹³ Successful preparation of

ω -arylpentadienals **15**¹⁴ or the dimethyliminium precursors such as **14**¹⁵ has been reported (Eq. 10), starting generally from an allylic alcohol, although there is one report of the use of diarylbutadienes such as **16** to give hydroxyfulvenecarboxaldehydes (Eq. 11).¹⁶

Formylation of dienes is much more successful when the double bonds are constrained in a ring, as with the bicyclic compound **17** (Eq. 12)⁸ or steroid **18** (Eq. 13).¹⁷ In the latter case, higher reaction temperature results in elimination of

acetic acid to give a 16,17-dehydro derivative. Cyclopentadienes give dimethylaminofulvenes, with further mono- or disubstitution, as illustrated by the preparation of compound **19** (Eq. 14).¹⁸ Two examples of the high yields which can be

obtained with acyclic dienes are those from alcohol **20** (Eq. 15)¹⁹ and the camphane derivatives **21** and **22** (Eq. 16).²⁰ All have terminal methylene groups and are hindered at the other terminus.

A range of acyclic trienes reacts at the end of the conjugated system (Eq. 17).^{16,21} The reaction with alcohol **23** illustrates the problems arising from double bond

migration (only product **I** is obtained at 100°; Eq. 18).¹⁹ Single products are obtained in good yields from steroidal trienes of type **24** (Eq. 19).²² Cycloheptatrienes²³ and the iron tricarbonyl derivative **25**²⁴ (Eq. 20) are formylated under normal conditions.

(Eq. 18)

(Eq. 19)

(Eq. 20)

Two examples of tetraenes reacting with Vilsmeier reagents are the acyclic example derived from alcohol **26** (Eq. 21)¹⁵ and the sesquiterpene **27** (Eq. 22).²⁵ In general, there seems to be no rule that predicts the stereochemistry engendered in the double bond which carries the formyl group for acyclic compounds.

(Eq. 21)

(Eq. 22)

Alkenes with Heteroatom Substituents

Enamines and Enamides. The electron-donating nitrogen atom in enamines and to a lesser extent in enamides makes for considerable reactivity

toward the Vilsmeier reagent. Simple enamines **28** provide a route to methinium salts (Eq. 23), and hence simple malonaldehydes.²⁶ It is necessary to be wary of the reactivity of the intermediate; the malonaldehyde synthon which is formed from a styrylenamine can be converted into a heterocycle, as in the formation of isoxazoles **29**, pyrazoles **30**, and pyrimidines **31** (Eq. 24).²⁷

Simple enamines of cyclic ketones were among the earliest examples to be studied, and allow the synthesis of cyclic β -ketoaldehydes (Eq. 25).²⁸ An example of

(Eq. 25)

reaction from an iminium salt **32** leads by bond migration to a pentamethinium salt (Eq. 26).²⁹ An enamine can still react even when there is an electron-withdrawing group at the β position (Eq. 27).³⁰ This equation shows the production of thioaldehydes.

Cyclization can occur as is seen in the production of quinolines **33** (Eq. 28).³¹ An enamine with a strongly electron-withdrawing substituent can still be converted into a polycarbonyl compound, as shown in the synthesis of compounds **34** and **35** (Eq. 29).^{32,33}

(Eq. 29)

With dienamines which are constrained in a ring as in the steroids **36** simple diformylation occurs (Eq. 30).^{34,35} The benzfulvene **37** and similar fulvenes may react as dienamines, or may, in their extreme resonance forms be considered

aromatic (Eq. 31).³⁶ From the iminium salt **38**, a monoformylated derivative is obtained, which is converted in good yield into pyridine-3-carboxaldehyde by treatment with ammonium chloride (Eq. 32).³⁷ A notable contrast is provided by the methyl derivatives of compound **38**; the first, **39**, gives *N,N*-dimethylaniline-2,4-dicarboxaldehyde (Eq. 33)³⁸ whereas the second, **40**, reacts with three moles of Vilsmeier reagent to give the polyiminium salt **41** and hence the naphthyridine **42** (Eq. 34).³⁹ In both cases the active methyl group becomes doubly substituted. With increasing numbers of conjugated double bonds in acyclic systems,

the complexity of products increases. By isolating the primary product as the diperchlorate, the masked tetraaldehyde **43** is obtained from 1,4-bis(dimethylamino)-1,3-butadiene in quite high yield (Eq. 35).⁴⁰

Enamides are excellent substrates for Vilsmeier reactions, possibly because of their lower reactivity. The acyclic carbamate **44** gives the acrylaldehyde in high yield, but stereochemical integrity is lost (Eq. 36).⁴¹ As in many Vilsmeier reac-

tions, a suitably placed neighboring group can react with the initial adduct to give a new ring; 2-pyridones **45** have thus been prepared (Eq. 37).⁴² With an alcohol

46 as starting material, dehydration by the reagent and subsequent Vilsmeier reaction gives an unsaturated aldehyde in excellent yield (Eq. 38).⁴³ A range of 3-formyl-1,4-dihydropyridines, such as compound **47**, can be obtained from a cyclic enamide (Eq. 39).^{41,44} As noted for enamines, dienes constrained in a ring provide uncomplicated reactions, as in the formation of the pyridine-3-carboxaldehydes produced from carbamate **48** (Eq. 40).^{44,45}

Enol Ethers and Enol Thioethers: Acetals and Ketals as Precursors of Enol Ethers. Reactivity of enol ethers is considerably lower than that of enamines so that product mixtures are less complex. Acetals or ketals react with the Vilsmeier reagent to generate enol ethers which can subsequently undergo formylation, although ambiguity is possible if the preliminary elimination is not regioselective. The simplest vinyl ethers react to give malonaldehydes, or more usually their dimethylamino derivatives such as **49** (Eq. 41),^{46,47} although the anils **50** can be isolated after treatment with aniline (Eq. 42).⁴⁶ By adding *N*-ethyl-4-methylquinolinium iodide, compound **51** is isolated as its perchlorate (Eq. 43).⁴⁸

Reaction with derivatives of 1,1-dialkoxyalkenes such as compound **52** gives α -formyl esters in reasonable yield (Eq. 44).⁴⁹ Cyclic vinyl ethers and enol ethers give generally cleaner reactions with good yields. Examples of the former are the dihydropyrans **53** (Eq. 45)⁵⁰ and of the latter the morphine derivative **54**

(Eq. 46)⁵¹ and the steroid **55** (Eq. 47).⁵² With additional unconjugated cyclic unsaturation, as in compound **56**, the products can be benzenedi- or tricarboxaldehydes although the yields are only fair (Eq. 48).⁵³

There are a few alkoxy⁵⁴ or trimethylsilyloxy⁵⁵ butadienes which react with the Vilsmeier reagent to give formylated products in moderate yields (Eqs. 49 and 50). In the latter case the products are isolated as aniline derivatives **57**.

Some simple cyclic diene ethers such as the benzopyran derivative **58** (Eq. 51)⁵⁶ and hexahydronaphthalene **59** (Eq. 52)⁵⁷ react normally; the majority of cyclic dienes used as substrates are steroids. The example given (**60**; Eq. 53)⁵⁸ is one of the few with a recorded yield, but it and other examples in Table VI show that a wide range of substituents can be tolerated.

In a number of cases the intermediate dimethylammonium salt has been reduced in situ by lithium borohydride to give a dimethylaminomethyl derivative (Eq. 53).⁵⁹ There is a report of the isolation of chloroformyl derivatives when an enol acetate was used.⁶⁰

There are a few examples of Vilsmeier reactions on vinyl sulfides, and yields can be good, as with the acyclic example **61** (Eq. 54)⁶¹ or the exocyclic olefin **62**

(Eq. 55).⁶² The vinyl thioethers shown in Eq. 55a demonstrate the use of deuterated DMF to produce deuterioaldehydes.^{62a} Reaction of 1,4-dithiine **63** gives a thiophene (Eq. 56).^{62b}

There is now general agreement that Vilsmeier reactions with acetals, ketals, and the corresponding thio derivatives proceed by loss of a molecule of alcohol or thiol to give the reactive unsaturated ether or thioether; with cyclic ketals the alcohol remains tethered, and may be chlorinated. The acetals and ketals are often more readily available than the unsaturated ethers, and yields of products are similar. A wide range of aliphatic and alicyclic acetals and ketals has been formylated; the reaction can tolerate bulky groups at either end of the double bond, as is shown for compound **64** (Eq. 57).^{63,64} Products are isolated as iminium salts

if dimethylamine is added during workup (Eq. 58)⁶⁵ or as dianils if an arylamine hydrochloride is added.⁶⁶ Reaction with 2-alkyl-1,3-dioxolanes such as **65** causes ring opening (Eq. 59).⁶⁷ Oxathiolanes react similarly, but 1,3-dithiolanes give products such as **66**, which must be formed by recyclization in a Michael fashion (Eq. 60).⁶⁷

A large number of polymethinium salts of type **67** have been prepared from acetals in 26 to 84% yields (Eq. 61).⁴⁸ Compound **51** can also be prepared in this

way (Eq. 43). Aldehydes with extended unsaturated chains can be obtained in two ways. In the first a polyether **68** is treated with the Vilsmeier reagent (Eq. 62)⁶⁸ and in the second, unsaturated acetals **69** or **70** are used (Eq. 63)⁶⁹ producing aldehydes up to nonatetraenedial.

(Eq. 63)

Interesting secondary products are pyridine, obtained in 55% yield after ammonium acetate is added to the Vilsmeier product from 1,1,3-triethoxybutane,^{37,70} and the cyclopentene **71** (Eq. 64).⁷¹

(Eq. 64)

Many examples use steroids as substrates. The simple 3-ketal **72** shows the generally preferred substitution in position 2 (Eq. 65).⁷² The diene **73** illustrates the successful use of a Vilsmeier reagent in the presence of a second reactive group (a methyl ketone; Eq. 66).⁷³ Steroid **74** with an exocyclic ketal shows that cyclization can occur to a suitable adjacent substituent (Eq. 67).³⁵

(Eq. 65)

(Eq. 66)

(Eq. 67)

Alkynes

There are not many Vilsmeier reactions reported for alkynes. Ethoxyacetylene gives the malonaldehyde derivative **75** (Eq. 68),⁷⁴ and arylalkynes give chlorocinnamaldehydes such as **76** (Eq. 69).⁷⁵ The use of the unusual reagent $\text{Ph}_3\text{P}\cdot\text{Br}_2$ with

DMF gives a bromocinnamaldehyde.⁷⁶ From a number of 1-buten-3-yne such as **77** a range of pentadienal derivatives can be prepared (Eq. 70)⁷⁷ and again $\text{Ph}_3\text{P}\cdot\text{Br}_2$ gives a 3-bromo derivative; addition of iodine and triphenylphosphine to the reaction mixture gives the 3-iodo derivative. The methoxy group in the product can be replaced using ethyl sulfide, phenyl sulfide, or dimethylamine.

Aldehydes and Ketones

The reactions between carbonyl compounds and Vilsmeier reagents have been thoroughly reviewed.³ It seems generally accepted that the enols are involved, with initial attack occurring on the double bond, and a final displacement of a derivative of the enolic hydroxy group by chloride or other halide (Eq. 71). There are few examples of reactions with aldehydes; one of the simple reactions is shown by butanal (Eq. 72).^{78,79} Conjugated aldehydes can give chloroiminium salts, but these are commonly treated with an amine (dimethylamine⁸⁰ or an aromatic amine⁶⁸) to give more easily handled products such as compound **78**

(Eq. 73). The use of an ether as the precursor to a conjugated aldehyde substrate is shown by the reaction of 2-methoxycyclohexancarboxaldehyde (**79**; Eq. 74).⁸¹

With acyclic and alicyclic ketones regiochemical complications can arise from alternative modes of enolization. With acyclic compounds there is the additional complication of geometrical isomers. Direction of enolization is usually in accord with thermodynamic stability; thus butan-2-one gives (*E*)-**80** and (*Z*)-**81** forms of 3-chloro-2-methyl-2-butenal (Eq. 75).⁸² Chain branching at the α or β carbon

can inhibit attack on the more stable enol such that ketones **82** (Eq. 76)^{68,83} and **83** (Eq. 77)⁸⁴ are formylated on the methyl group rather than on the methine or methylene groups, while **84**, with a tertiary α -carbon, shows a high *E*:*Z* ratio (Eq. 78).⁸⁵ The first of these three examples involves diformylation.

The expected direction of enolization is shown by β -ketoesters, such as methyl acetoacetate (Eq. 79)⁸² and the benzyl ketone **85** (Eq. 80).⁸² *Z*:*E* ratios have been recorded in detail by several groups.^{82,86,87}

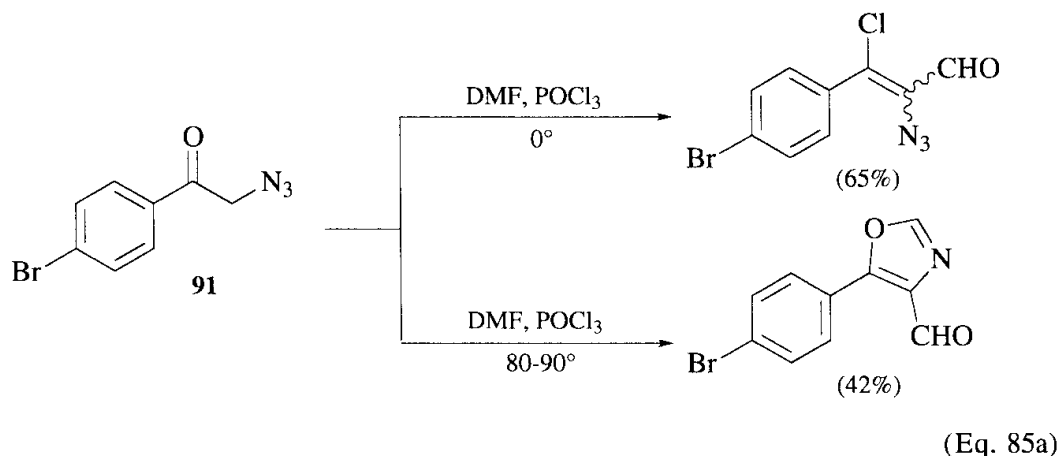

Vilsmeier reactions on 1,3-diketones, 1,4-diketones, and conjugated enones give cyclic products as shown by the reactions of compounds **86** (Eq. 81),⁸⁸ **87** (Eq. 82),⁸⁹ and **88** (Eq. 83).³⁸ The reaction of the Vilsmeier reagent with α,β -epoxy ketones also gives benzaldehydes or 1,3-phthalaldehydes (Eq. 83a);

cyclohexenone epoxides also give simple benzaldehydes.^{89a} The reaction of γ -ketoesters such as compound **89** is normal (Eq. 84).⁹⁰

A large number of reactions have been reported between Vilsmeier reagents and acetophenones, their vinylogs, and polycyclic and heterocyclic analogs. Acetophenone itself illustrates the production of β -halocinnamaldehydes **90**,⁹¹⁻⁹³ although higher yields can be obtained if the dimethylamino intermediates are isolated and subsequently hydrolyzed (Eq. 85).⁷¹ There is normal reaction with ω -azidoacetophenones such as **91** and the Vilsmeier reagent at room temperature giving chloroenals, but at higher temperatures loss of nitrogen occurs, producing oxazoles (Eq. 85a).^{93a,93b} In the latter reaction, the ω ,4-bromoacetophenone can be used in a one-pot reaction where sodium azide in DMF is added first, then the phosphoryl chloride. A route to quinolines has been found from 2-azidoacetophe-

ones and homologs. In the example shown azidoketone **91a** reacts to give a mixture of a 2-dimethylamino-4-chloroquinoline and the 3-formyl derivative (Eq. 85b).^{93c,93d} Other 2-amino groups are obtained from other Vilsmeier amides. An α -methyl substituent (as in propiophenones) has little inhibitory effect on yield.⁹⁴

In view of the ability of the Vilsmeier reagent to attack aromatic rings, especially those activated by electron-donating groups, it is instructive to note the formation in high yield of the cinnamaldehydes **92** when *meta*-, or *para*-methoxyacetophenones (Eq. 86),⁹⁵ or even *para*-dimethylaminoacetophenone are used.³³ Similarly, an acetylpyrazole,⁹⁶ 3-acetylindole (**93**, Eq. 87),⁹⁷ and acetylferrocene (**94**, Eq. 88)⁹⁸ react to give chloroenals without nuclear substitution.

By contrast, pyrroles are sufficiently reactive that formylation normally proceeds both on nucleus and side chain. An unusual result is shown in the reaction of compound **95** (Eq. 89).⁹⁹

With a suitably reactive ortho substituent, cyclization can follow Vilsmeier reaction to give chromones. From 2-hydroxyacetophenones **96** the products are 3-formylchromones (Eq. 90),¹⁰⁰⁻¹⁰² and from the propiophenone **97** a 3-methylchromone is formed (Eq. 91).¹⁰³ The reaction is equally successful with

the three isomeric *o*-hydroxyacetylnaphthalenes.^{100, 104} A variant uses the BF_3 complex of *o*-hydroxyacetophenones.¹⁰⁵ There are numerous examples of this modification in the patent literature.¹⁰⁶⁻¹¹² In the example shown (Eq. 92), the

(Eq. 92)

normal product **98** is accompanied by a second, **99**, derived from an alternative cyclization.¹⁰⁵ An adjacent fluorine atom has also been reported to be involved in the cyclization during Vilsmeier reaction of pentafluoroacetophenone (**100**); here the intermediate malonaldehyde derivative was isolated and subsequently cyclized (Eq. 93).^{112a} A synthesis of quinolines makes use of an adjacent amine or

(Eq. 93)

acetylamine to give a 4-chloroquinoline-3-carboxaldehyde (Eq. 93a).^{112b,112c} Acetylation of the starting material improves the yields, but some 4-chloroquinoline is also formed, and this becomes the major product when the ketone side chain is extended.

It is possible to formylate α -diazoketones, albeit in usually poor yield, by keeping the reaction mixture between -10° and room temperature; one of the better yields is shown in Eq. 93b.^{112d}

Alicyclic ketones, even cyclobutanone,⁷¹ react well with Vilsmeier reagents without the ambiguity of stereochemistry observed in acyclic examples. Thus cyclohexanone **101** gives a chloroenal¹¹³ as does *N*-benzoylpiperidone (**102**; Eq. 94).¹¹⁴ The products may be converted into the synthetically useful ketal

103.¹¹⁵ In a number of cases^{116,117} the crude chloroenal has been converted into a pyrimidine **104** (Eq. 95).¹¹⁶ With a higher ratio of Vilsmeier reagent to substrate, reaction occurs twice via intermediates of type **105** to give compounds of type **106** (Eq. 96).¹¹⁸ Earlier workers⁷¹ had reported a dimethylamino derivative, but the later authors could not repeat this.

(Eq. 95)

(Eq. 96)

The introduction of substituents into the ring of cyclic ketones produces problems of regiochemistry. A number of methylcycloalkanones have been used in Vilsmeier reactions, and there is a tendency for the double bonds to be formed preferentially away from the substituent if it is in the β position to the carbonyl group, as shown for a number of cycloalkanones (Eq. 97).¹¹⁹ The effect is negligible if the substituent is further away. Introduction of additional unsaturation

(Eq. 97)

gives varying results in steroid systems such as the enone **107** (Eq. 98),¹²⁰ whereas from simple cyclohexenones benzene derivatives such as compound **108** are formed (Eq. 99).¹²¹ Cyclohexane-1,3-dione has been reported to give benzene derivative **109**,¹²² as well as non-benzenoid derivatives **110**¹²² and **111**^{123,124} (Eq. 100).

(Eq. 98)

(Eq. 100)

Cyclic ketones with a fused aromatic ring usually form chloroenals without side reaction, as in the case of compounds **112**^{125,126} and heteroatom-substituted analogs such as compounds **113** (Eq. 101);^{127,128} 2-indanone gives the iminium compound **114** (Eq. 102).³⁶

(Eq. 101)

(Eq. 102)

A number of examples involving cyclic ketones with fused heteroaromatic rings are reported. Among the few that react normally are the heterocycles **115** (Eq. 103)¹²⁹ and the pyridine derivative **116** (Eq. 104),¹³⁰ where monofunctional-

ization is reported. When the fused heterocycle is π -excessive, formylation can occur on the heterocyclic ring as in the dihydroindole **117** (Eq. 105).¹³¹ While the pyrazole **118** gives a normal product (Eq. 106), the closely related compound **119** gives an abnormal reaction,¹³² other compounds are reported to react normally.¹³³

Anthrone **120** (R = H) reacts like an enone giving an anthracene derivative,¹³⁴ but 1,8-dihydroxyanthrone **120** (R = OH), with the unusual combination of

benzoyl chloride and DMF, gives a mixture of methylene derivatives (Eq. 107).^{134a} Other Vilsmeier reagents using phosphoryl chloride give only aminomethylene derivatives.^{134b} The reaction of indane-1,3-dione with the vinylogous aza-Vilsmeier reagent gives compound **121** (Eq. 108).¹³⁵

Imines, Hydrazones, Semicarbazones, and Oximes

In most of the examples of this type the C=N bond provides activation for an adjacent methyl or methylene group; three products can be obtained from the cyclic imine **122**. The least substituted product **123** is only obtained at low temperatures; at higher temperatures products **124** and **125** are obtained, the proportion of the latter increasing as the POCl₃ proportion is raised (Eq. 109).^{136,137} From

hydrazones and semicarbazones cyclization of the first-formed product gives a pyrazole. Thus the phenylhydrazone **126**,¹³⁸ or semicarbazone **127**,¹³⁹ give pyrazoles **128** and **129**, in the latter case with loss of the amide group (Eq. 110), often

in excellent yields, presumably via a malonaldehyde derivative. *N,N*-Disubstituted hydrazones without methylene groups adjacent to the imine bond are mainly formylated to give compounds **130**¹⁴⁰ but have also been reported to give isomeric ketones **131** such as (Eq. 111).^{141,140}

Cyclization to give pyridazinones is observed when the hydrazones **132** and **133** are treated with the Vilsmeier reagent (Eq. 112).¹⁴² Methyl substituents on a

number of dihydropyrazoles are converted into malonaldehyde derivatives **134** (Eq. 113).^{143,144} Chlorination at C5 also occurs if the oxo derivative is used. The

unusual cyclization of hydrazone **135** gives the quaternary salt **136** in high yield (Eq. 114).¹³⁸ There is an example where an oxime has survived the normal Beckman rearrangement, or, in the case of aldoximes, dehydration to give cyanides. From the steroid **136a** the unsaturated aldehyde **136b** is obtained at 0°, with more normal formation of a 2-chloropyridine via the Beckman rearrangement product at 65° (Eq. 114a).^{144a}

Carboxylic Acids, Anhydrides, and Acid Chlorides

The reaction of derivatives of acetic acid (or its salts) with the Vilsmeier reagent is widely used to prepare malonaldehydes or their derivatives. The simple haloacetic acids **137** (or their salts) give fluoro-¹⁴⁵ or chloromalonaldehyde derivatives^{74,146} or chloro- or bromotriformylmethane derivatives (Eq. 115).^{74,146}

(Eq. 115)

This reaction has been exploited using arylacetic acids; yields are excellent when the products are isolated as dimethylamino derivatives as shown for compound **138** (Eq. 116).¹⁴⁷ Malonic acids such as **139** are thus converted into derivatives of malonaldehyde in moderate yields (Eq. 117)¹⁴⁸. Cyanoacetyl chloride gives deriva-

tives of acrylonitrile¹⁴⁵ or acrylic acid.⁷⁴ Reactions with *N*-substituted glycines produce derivatives of aminomalonaldehyde, as shown for compound **140** (Eq. 118).¹⁴⁹

The only notable side reactions are the formation of substituted indoles, benzofurans, and benzthiophenes from diacids (Eq. 118a),^{149a} the isoquinoline **141**

(Eq. 118a)

from 2-carboxyphenylacetic acid (Eq. 119)¹⁵⁰ (some of the benzopyranedione **142** may also be formed), the indenone **143** from 1,2-bis(carboxymethyl)benzene (Eq. 120),³⁶ and the lactones **144** and **145** from 2-hydroxyphenylacetic acid (Eq. 121).¹⁵¹

Acyclic dienoid acids and cyclohexa-2,5-dienecarboxylic acids give a variety of benzaldehydes. An example of the former class is acid **146** (Eq. 122)¹⁵² and of the latter, acid **147** (Eq. 123).¹⁵³ A few examples exist of the preparation of malon-

aldehyde derivatives from acid chlorides;¹⁵⁴ it should be noted that the Vilsmeier reagent is often used as a mild reagent to prepare acid chlorides at low temperatures. The anhydride **148** reacts in a manner similar to lactams to give compound **149** in low yield (Eq. 124).¹⁵⁵

(Eq. 124)

Esters and Lactones

Almost all examples of Vilsmeier reactions on esters use activated acetic esters bearing a second electron-withdrawing group, as in diethyl malonate **150** and ethyl cyanoacetate **151** (Eq. 125),¹⁵⁶ or an electron-deficient heterocyclic ring as

(Eq. 125)

in quinoline-2-acetate **152**,¹⁵⁷ but the electron-rich 2-indolylacetate **153** has also been reported¹⁵⁸ to react in good yield (Eq. 125). One lactone has been converted into a dichloro enal **154** (Eq. 126).¹⁵⁹ The most remarkable reaction gives a formyl derivative **155** from ethyl diazoacetate, although some decomposition occurs (Eq. 127).¹⁶⁰

(Eq. 126)

(Eq. 127)

Amides and Lactams

Lactams that may be regarded as tautomers of hydroxyheteroaromatics were included in the chapter in volume 49.¹ Simple amides react with the Vilsmeier reagent like other carbonyl compounds to form mono- or diformyl derivatives, but such simple cases are rare; an example is provided by the synthesis of compound **156** (Eq. 128).⁷⁴ An amide with an α hydrogen can function both as Vilsmeier re-

agent precursor and as substrate with phosgene to give compounds such as **157** (Eq. 129).¹⁶¹ The modified Vilsmeier conditions, using formamide and phospho-

ryl chloride, can be used to form pyrimidine **158** from dimethylacetamide, although yields of such reactions are usually lower than that shown (Eq. 130).¹⁶²

From acetanilides or *N*-acetylaminothiophenes a range of fused pyridines can be formed. Variants shown are compounds **159** (Eq. 131),¹⁶³ **160** and **161** (Eq. 132),^{164,165} **162** (Eq. 133),^{166,167} and **163** (Eq. 134).¹⁶⁸ Compounds of type **162** (Eq. 133) can also be obtained from an acetophenone oxime via an initial Beckmann rearrangement.¹⁶⁹ 2,5-Dimethyl-3-acetamidothiophene gives thieno[3,4-*b*]pyridines.^{164,165} Acetamidopyrazoles have also been used in reactions analogous to that shown in (Eq. 132).¹⁷⁰

When the alkyl chain is extended¹⁷¹ or is an arylacetyl group,¹⁷² a 3-alkyl- or 3-aryl-2-chloroquinoline **164** is the product (Eq. 135). With 3-substituted

anilides there is the possibility for formation of two isomeric products, but in the cases recorded the products are always 7-substituted quinolines. The oximes of 4-arylbut-3-en-2-ones, which are vinylogs of acetophenones, give 2-chloro-5-arylpyridine-3-carboxaldehydes under Vilsmeier conditions.^{144a} Only one example of the use of phosphoryl bromide with acetanilides is recorded, giving the

2,5-dibromoquinoline **165** in poor yield (Eq. 136).¹⁷¹ Cyclohexenes such as compound **166** give 2-pyridones in poor to moderate yields (Eq. 137).¹⁶⁸ Cycliza-

tion has been reported to occur to an adjacent carboxy group to produce an azepinedione,¹⁷³ where the aromatic ring can be benzene, pyridine, or thiophene, but a later report of this reaction shows that the products are benzo[*d*]oxazinones such as **167** (Eq. 138).^{173a,174}

N-Acylureas or thioureas such as **167a** react with elimination of the urea and formation of malonaldehyde derivatives, isolated as perchlorates (Eq. 138a).^{174a} *N*-Acetylurea does not react.

(Eq. 138a)

As mentioned earlier, lactams that are potentially aromatic by tautomerism are dealt with elsewhere.¹ Simple lactams normally react to give compounds such

as **168**¹⁷⁵ although a quantitative yield of chloroaldehyde **169** is reported in one case (Eq. 139).¹⁷⁶ A few examples of reactions with azasteroids are reported, as exemplified by compound **170** (Eq. 140),¹⁷⁷ although yields are generally poor.

Monocyclic lactams containing other heteroatoms, such as compound **171**, give chloroaldehydes (Eq. 141).^{178,179} There are numerous examples of Vilsmeier reactions with lactams fused to benzene rings; representative products are **172**^{178,179} and **173**¹⁸⁰ (Eq. 142), **174** (Eq. 143),¹⁸¹ **175** (Eq. 144),¹⁸² and **176** (Eq. 145).¹⁸¹

(Eq. 143)

(Eq. 144)

(Eq. 145)

Imides

Vilsmeier reagents react with *N*-substituted succinimides to give pyrroles **177** (Eq. 146).¹⁸³ Glutarimides can give monoformyl derivatives **178** or diformyl

(Eq. 146)

derivatives **179** (Eq. 147).^{184,185} In the latter case, yields are higher when the dimethylaminomethyl compounds **180** are isolated.¹⁸⁶ The α,α -disubstituted glutarimide **181** gives a pyridine when treated with the Vilsmeier reagent at high temperature (Eq. 148).¹⁸⁷ Monoformylation of an isoquinolinedione proceeds in high yield with DMF to give compound **182**; an anilinomethylene derivative **183** is obtained when the Vilsmeier reagent from formanilide is used (Eq. 149).¹⁸⁸

Nitriles

Acetonitrile gives the cyanomalonaldehyde derivative **184** (Eq. 150).¹⁴⁵ Malononitrile provides an example of a Vilsmeier reaction at both nitrogen and

carbon to give the iminium salt **185** (Eq. 151), which with ammonia gives pyrimidine **186** (Eq. 152);¹⁸⁹ aniline or *N*-methylaniline convert the intermediate into the 4-phenylamino- and the 4-[phenyl(methyl)amino]pyrimidines. Cyanoacetyl

chloride¹⁴⁵ and ethyl cyanoacetate¹⁹⁰ form the corresponding dimethylaminomethylene derivatives **187** and **188** by condensation with the activated methylene group (Eq. 153). Cyanoacetamides, depending on the pattern of substitution, can react with phosphoryl chloride to give pyridines such as **189** (Eq. 154) or **190** (Eq. 155)¹⁹¹ or 4,6-dichloropyrimidines **191**¹⁹² alone (Eq. 156) or, as with

192, mixed with 6-chloro-4-pyrimidinones **193** (Eq. 157).¹⁹³ In these reactions, the cyanoacetamides act as precursors and substrates for the Vilsmeier reaction.

Aryl- and heteroarylacetonitriles give compounds of type **194** (Eq. 158).¹⁵⁷ When the aryl group is π -excessive (azulene or heteroaryl) and vinamidinium

salts **195** are used, cyclization to the aromatic ring producing benzannulated compounds such as **196** (Eq. 159) can occur.¹⁹⁴ A similar reaction with *N*-unsubstituted pyrrole **197** gives an indolizine **198**, whereas the azavinamidinium salt **199** gives an azaindolizine (Eq. 160).¹⁹⁴

2-Cyanomethylthiopyrimidines react with the Vilsmeier reagent giving thiazolopyrimidinopyrimidines **200** and **201** if the substituent at position 4 in the pyrimidine is methyl or trifluoromethyl; if the substituent is hydrogen a bicyclic product is formed (Eq. 161).¹⁹⁵

In α,β -unsaturated nitriles, reaction can occur at a vinylogous methylene group, as in example **202**, to give a 2-chloro-3-cyanopyridine (Eq. 162).¹⁹⁶ Yields are poor, but are much better with the vinylogous cyanoacetates such as compound **203**.¹⁹⁷ Aminopyrimidines **204** can be obtained from arylcyanocarbonyl compounds, using formamide and phosphoryl chloride (Eq. 163).¹⁹⁸ Yields, when quoted, are very poor.

Methyl and Methylene Groups Activated by Adjacent Aromatic and Heteroaromatic Rings

In most of the examples in this section, the aromatic ring is π -deficient or positively charged. The products are mono- or diformylated, and are often

isolated as the aminomethylene derivatives. A typical reaction is that of 4-methylpyridazine (**205**; Eq. 164).¹⁹⁹ Other neutral monocyclic activating rings

are isoxazole,²⁰⁰ 1,3,5-triazine,^{201,202} pyrimidine (2-²⁰³ or 4-substituted²⁰⁴), pyrazine,²⁰⁵ pyridine (4-substituted),²⁰⁶ and benzene.²⁰⁷ Bicyclic neutral activating rings are 1,2-dithio-[1,5-*b*]dithiole,²⁰⁸ imidazo[4,5-*e*]pyrimidines,²⁰⁹ benzimidazoles,²¹⁰ benzoxazole,²¹¹ benzthiazole,²¹² benzisothiazoles,²¹² benzselenazoles,²¹¹ pyrrolo[2,3-*a*]pyrimidine,²⁰⁹ indole,²¹³ azulene,²¹⁴ benzpyrimidinone,²¹⁵ benzpyrazinethione,²¹⁶ quinoline (2- and 4-substituted),²¹¹ benzpyranone,²¹⁷ and naphthalene.²¹⁸ Charged monocyclic rings which activate methyl groups are exemplified by the pyrylium salt **206** (Eq. 165).²¹⁹ Other activating rings are ditholium,²²⁰

pyrimidinium,²²¹ oxazinium,²²² and cycloheptatrienylium.²²³ Bicyclic charged ring systems used are thiazolo[3,2-*a*]pyrimidinium,²²⁴ benzoxazolium,²¹¹ benzthiazolium,²²⁵ benzselenazolium,²¹¹ benzpyrimidinium,²¹⁵ quinolinium (2- and 4-substituted),²¹¹ benzpyrylium,²¹⁹ benzthiopyrylium,²¹⁹ and a naphthopyrylium.²¹⁹

Some comment on benzene activation may be useful. Several activating groups are required, which may be on the benzene nucleus as shown in example **207** (Eq. 166),²⁰⁷ or on the side chain, as in compound **208** (Eq. 167).²¹⁸ Naphthalenes

behave similarly, as shown by compound **209** (Eq. 168).²¹⁸ Azulenes require no additional activation for substituents on the seven-membered ring, as shown by the reaction of compound **210** (Eq. 169);²²⁶ formylation also occurs on the electron-rich five-membered ring.

It is surprising to see reaction in a methylindole **211**; the product is also unusual (Eq. 170).²¹³ Many products are described for the reaction between

N-methyl-1,2,3,4-tetrahydrocarbazole and the Vilsmeier reagent, with formylation on saturated and aromatic rings, dehydrogenation, and even introduction of a carbonyl group.²²⁷

Secondary products are obtained when adjacent active sites or groups are present, such as the tricyclic compound **212**, which is formed when the Vilsmeier reagent from dimethylthioformamide reacts with a dithiolium salt (Eq. 171).²²⁰ Reaction at the pyrimidinyl methyl group in compound **213** results in formation of a pyrrolopyrimidinecarboxaldehyde (Eq. 172),²²⁸ and a similar reaction is seen with pyrazine **214** (Eq. 173).²²⁹ Vilsmeier reaction of tetrahydroisoquinoline **215** gives a mixture of three products, two arising from cyclization (Eq. 174).²³⁰ Cy-

clization to a more remote amino group is observed in the reaction of salt **216** (Eq. 175).²²⁴ It should be noted that since the primary products are malonaldehyde derivatives, the addition of a suitable reagent can be used to generate a new

five-membered aromatic ring as shown by the synthesis of compounds **217** to **219** (Eq. 176).²⁰⁹ Cyclization to an adjacent carboxy group gives a pyridinone **220** (Eq. 177)²³¹

COMPARISON WITH OTHER METHODS

Because of the wide variation in reactions between the Vilsmeier reagent and these different non-aromatic substrates, ranging from the production of β -chloroaldehydes via malonaldehydes to quinolines and chromans, the usual comparison with other methods cannot be made. Each separate class of product would require its own set of comparisons, and this would tax the patience of authors, editors, and readers.

EXPERIMENTAL CONDITIONS

By far the most common experimental procedure for the Vilsmeier reaction involves DMF, usually in excess and acting as the solvent, and POCl₃ (**Note**; the formation of the reagent is exothermic and cooling in ice water is necessary). The coreagent is added and the reaction often proceeds at room temperature. In the Tables, the temperature of reaction is specified only when the products vary with variation in the temperature. Solvents (usually chlorinated hydrocarbons) are occasionally used. It is possible to prepare the solid Vilsmeier salt and use this in the reaction, but there is usually no obvious advantage. Acid chlorides other than POCl₃ have been used, notably oxalyl chloride and carbonyl chloride (phosgene); the latter seems to offer little advantage, particularly in view of its toxicity. It would be interesting to see more use of pyrophosphoryl chloride (an example is given in *Procedures*), which has been claimed to offer enhanced activity in the formylation of aromatic systems.¹ Bromide can be introduced into Vilsmeier products by using POBr₃ although PBr₃ is said to be as efficient.⁹² The most commonly used amide after DMF is *N*-methylformanilide, which was used in Vilsmeier's first experiments. The most common workup procedure is with an aqueous base (sodium acetate, sodium or potassium hydroxide), but in many cases better yields are obtained if the intermediate iminium salt is isolated (perchlorate or hexafluorophosphate) and hydrolyzed in a subsequent step.

EXPERIMENTAL PROCEDURES

4-Methoxy- α -(4-methoxyphenyl)cinnamaldehyde (Formylation of an Alcohol as a Precursor of an Alkene).²³² To a solution of deoxydihydroanisoin (2.6 g, 10.1 mmol) in DMF (20 mL) was added POCl₃ (9 g, 58.63 mmol) dropwise with stirring and the reaction mixture was heated at 100° for 14 hours. The iminium complex was decomposed with sodium acetate (27 g) in water (70 mL) and the product was extracted with ether (3 × 30 mL). Removal of the solvent afforded the aldehyde (2.65 g, 98%), which was recrystallized from benzene-hexane: mp 120°; IR (Nujol) 2850, 1675 cm⁻¹; UV(EtOH) 233 (log ϵ = 4.25), 323 (4.27) nm; ¹H NMR (CDCl₃) δ 3.73 (s, 3 H), 3.80 (s, 3 H), 6.63–7.23 (m, 9 H), and 9.63 (s, 1 H). Anal. Calcd. for C₁₇H₁₆O₃: C, 76.0; H, 6.0. Found: C, 75.9; H, 6.2.

α -(*n*-Propyl)-3,4-methylenedioxy-2-(*n*-propyl)cinnamaldehyde (A) or 1-Dimethylamino-5,6-methylenedioxy-2-(*n*-propyl)indene (B) (Reaction with a Styrene).¹¹ a) To a mixture of POCl₃ (3.85 g, 0.025 mol) and DMF (7.3 g, 0.061 mol) was added at 20°, α -(*n*-propyl)-3,4-methylenedioxy-2-(*n*-propyl)styrene (4.75 g, 0.03 mol), and the mixture was heated to 55°, maintained at this temperature during the exothermic reaction, and then heated at 75–80° for 1 hour. The reaction mixture was poured into aqueous sodium acetate and heated at 70–75° for 1 hour. The cooled mixture was extracted with ether, the organic extracts were dried, and then concentrated. The cinnamaldehyde (A) was obtained (2.6 g, 48%): bp 115–117° (0.1 mm); Anal. Calcd. for C₁₃H₁₄O₃: C, 71.55; H, 6.42. Found: C, 71.24; H, 6.35.

b) To a cooled (ice bath), round bottom flask containing DMF (45 g, 0.61 mol) was added dropwise with stirring POCl₃ (18.4 g, 0.12 mol). The mixture was stirred in an ice bath for 15–20 minutes and the α -(*n*-propyl)-3,4-methylenedioxy-2-(*n*-propyl)styrene (19.1 g, 0.10 mol) was added dropwise. After the addition, the reaction mixture was immediately heated on a steam bath for 3 hours. The resulting black mixture was poured into 400 mL of ice-H₂O and unreacted olefin was removed by extraction with two 175 mL portions of Et₂O. The aqueous layer was made basic by the addition of 10% aqueous NaOH solution and extracted with three 150 mL portions of Et₂O. The combined ether extracts were dried over anhydrous MgSO₄ and concentrated under reduced pressure. The aminoindene (B)

was distilled, bp 125–127.5° (0.25 mm), converted into the stable HCl salt, then recrystallized (19.98 g, 71%): mp (from EtOH-Et₂O) 177–178°; ¹H NMR (CDCl₃) δ 4.82 (1 H), 6.01 (2 H), 6.61 (1 H), 6.77 (1 H), 7.50 (1 H) among others.

Methyl 3-Amino-2-thioformylcrotonate (Thioformylation of an Enamine).³⁰ A solution of POCl₃ (0.5 mL, 5.5 mmol) in DMF (1.5 mL) was added dropwise during 10 minutes to a stirred solution of methyl 3-aminocrotonate (0.575 g, 5 mmol) in THF (10 mL) with the temperature maintained at 0°. The resulting mixture was stirred for a further 1 hour at room temperature and then for 4 hours at 30°; it was then allowed to stand overnight in a refrigerator. Addition of ether in portions at 0° precipitated a highly hygroscopic yellowish white to yellow solid from which ether was removed by decantation. The remaining solid was washed several times with ether until the ether layer became clear. The solid was then dissolved in dichloromethane (250 mL) in a separating funnel (1 L) and to the solution was added aqueous sodium hydrogen sulfide (2 M; 25 mL). The mixture was shaken vigorously, separated, and the water layer extracted with further dichloromethane (30 mL). The combined organic extracts were washed six times with water, dried (MgSO₄), and concentrated to give orange crystals. The thioformyl derivative was crystallized from benzene-hexane, mp 110.5–111° (0.66g, 83%): IR(KBr) 3300, 1643, 1442, 1361, 1279, 1248, and 1030 cm⁻¹; UV (EtOH) 216 (log ε = 4.17), 256 (4.09), and 354.5 nm (4.32); ¹H NMR (CDCl₃) δ 13.94 and 6.83 (1 H, each br s, NH₂), 10.97 (1 H, s, CHS), 3.79 (3 H, s, OCH₃), and 2.58 (3 H, s, CH₃). Anal. Calcd. for C₆H₉NO₂S: C, 45.3; H, 5.7; N, 8.8; S, 20.1. Found: C, 45.5; H, 5.9; N, 8.9; S, 20.0.

2,4-Diphenyl-3-formyl-4H-chromene (Formylation of an Unsaturated Ether).²³³ To a solution of 2,4-diphenyl-4H-chromene (2.84 g, 0.01 mol) in 10 mL of anhydrous DMF was added POCl₃ (1.1 mL). The mixture was kept on a boiling water bath for 3 hours and then added to 150 mL of a 5% aqueous solution of sodium hydroxide. The separated reaction product was extracted with ether. The organic layer was dried with sodium sulfate, and the solvent was distilled on a water bath. The residue was crystallized from propyl alcohol (10 mL) to give the title product, mp 144–145° (2.93 g, 94%). IR (Nujol) 1665, 1620, 1600, 1590, 1220 cm⁻¹. ¹H NMR (CDCl₃) δ 5.10 (s, 1 H), 6.82–7.73 (m, 14 H), 9.48 (s, 1 H). Anal. Calcd. for C₂₂H₁₆O₂: C, 84.59; H, 5.16. Found: C, 84.78; H, 5.26.

2-Chlorocyclohex-1-ene-1-carboxaldehyde (Formylation of a Cyclic Ketone). A detailed procedure for this reaction is described in *Organic Syntheses*.¹¹³ The yield of the chlorocyclohexenecarboxaldehyde was 53–74%.

3-Dimethylamino-2-(4-methylphenyl)prop-2-en-1-dimethyliminium Perchlorate (Diformylation of 4-Methylphenylacetic Acid; Isolation as Dimethyliminium Perchlorate).²³⁴ POCl₃ (27 mL, 0.3 mol) was dropped slowly into DMF (36.5 g, 0.5 mol) with cooling and stirring. The solution was cooled to -10° and 4-methylphenylacetic acid (15 g, 0.1 mol) was added in small portions. The syrupy slurry was stirred for 1 hour at room temperature, and then 2 hours at 60° and finally 5 hours at 80° . After removing excess solvent under vacuum on a water bath, the dark brown syrup was decomposed cautiously with cooling in a beaker with water (20 mL), cooled to -10° , and 30 mL of 70% perchloric acid and 400 mL of ether were added. After cooling in solid CO₂ the precipitate was quickly collected by filtration and washed with ether. The iminium perchlorate was crystallized from methanol/ether, mp 164° (28.8 g, 91%).

2-Chloro-7-methoxyquinoline-3-carboxaldehyde (Formylation of an Amide with Cyclization to a Quinoline).¹⁶⁶ DMF (9.13 g, 9.6 mL, 0.125 mol) was cooled to 0° in a flask fitted with a drying tube and POCl₃ (53.7 g, 32.2 mL, 0.35 mol) was added dropwise with stirring. To this solution was added 3-methoxyacetanilide (8.25 g, 0.05 mol) and after 5 minutes the solution was heated under reflux for 4 hours. The reaction mixture was poured into ice-water (300 mL) and stirred for 30 minutes at $0-10^{\circ}$. The aldehyde was filtered off, washed well with water, and recrystallized from ethyl acetate, mp $197-198^{\circ}$ (9.85 g, 89%). Anal. Calcd. for C₁₁H₈ClNO₂: C, 59.6; H, 3.6; N, 6.3. Found: C, 59.9; H, 3.6; N, 6.2.

2-(6-Puriny)malonaldehyde (Diformylation of a Reactive Methyl Group).²⁰⁹ DMF (30 mL) was cooled to 0° and POCl₃ (50 mL) was slowly added with stirring. 6-Methylpurine (13.4 g, 0.1 mol) was added slowly at 5° with stirring to this previously prepared reagent. The mixture was maintained at 5° for 15 minutes with continuous stirring, then at 25° (1 hour). The mixture was then heated slowly to 120° (oil bath) and kept at this temperature for 1 hour. The thick syrup that resulted was cooled to 60° and poured onto crushed ice with vigorous stirring. Solid sodium carbonate was added to adjust the pH to 3 and the volume brought up to 500 mL by addition of cold water. This solution (50 mL, equivalent to 0.01 mol of 6-methylpurine) was cooled to 5° and sodium hydroxide (2 g) was added slowly with stirring. Charcoal was added, the solution was filtered, and the filtrate was acidified with glacial acetic acid to pH 5. The crystalline precipitate was collected, washed with water, and dried, to yield the title product as thin needles (1.55 g, 82%), mp 330° (dec.). The malonaldehyde could be further purified by repeated treatment with alkali followed by glacial acetic acid precipitation, mp 330° (dec.). IR 1667 cm⁻¹; ¹H NMR (CF₃CO₂H) δ 9.7 (s, 2 H), 9.48 (s, 1 H), 9.25 (s, 1 H). Anal. Calcd. for C₈H₆N₄O₂: C, 50.5; H, 3.2; N, 29.5. Found: C, 50.4; H, 3.3; N, 29.3.

4-Oxo-4H-1-benzopyran-3-carboxaldehyde (Use of Pyrophosphoryl Chloride).¹⁰¹ To a stirred solution of *o*-hydroxyacetophenone (25 g, 0.184 mol) in 80 mL of DMF, 80 mL of (Cl₂PO)₂O was added dropwise at -20° during about 10 minutes. The mixture was stirred at room temperature for 13 hours, and decomposed by ice-water. The resulting precipitate was collected by filtration, washed with H₂O and then EtOH, and recrystallized from acetone to afford the benzopyrancarboxaldehyde (19.6 g, 61%) as colorless crystals, mp 152–153° (lit. 152°). From the ethanol washings a small amount (430 mg) of *trans*-1-(2-hydroxybenzoyl)-2-(4-oxo-4H-1-benzopyran-3-yl)ethylene, mp 177–179° (from acetone) was isolated.

2-Bromocyclohex-1-ene-1-carboxaldehyde (Use of PBr₃ to Produce a 2-Bromoenal).⁹² A solution of DMF (10.97 g, 0.15 mol) in anhydrous CHCl₃ (40 mL) was cooled with ice and stirred while distilled PBr₃ (34.0 g, 0.125 mol) was added dropwise. After a while the white crystalline adduct precipitated. Then a solution of cyclohexanone (4.2 g, 0.05 mol) in CHCl₃ (20 mL) was added to the reaction mixture with stirring. The mixture was stirred at 20° (12 hours), then the CHCl₃ was evaporated in vacuo and the oily residue was decomposed with ice (ca 100 g) taking care that the mixture did not warm up excessively. The cold mixture was then neutralized with solid sodium hydrogen carbonate and left standing to reach room temperature. The product was then extracted with ether, the extract washed well with water and with a saturated solution of K₂CO₃ to a negative reaction with FeCl₃, and dried over anhydrous MgSO₄. Ether was removed by distillation through a Widmer column (30 cm in length), and the product was isolated by vacuum distillation b.p. 51°/0.7 mm, (4.73 g, 54%); IR (CCl₄) 3343, 2740, 1683, 1620, 1386 cm⁻¹; UV (cyclohexane) 262 nm (log ε = 4.023); UV (EtOH) 260 nm (log ε = 3.961).

TABULAR SURVEY

We have attempted to cover thoroughly the literature until the end of 1998. Only carbon-carbon bond formation reactions are included in the Tables. Where a reaction has been reported by different workers, the yield in the Table corresponds to that reported in the first reference.

Some oximes appear in Table XV when they clearly undergo Beckmann rearrangement prior to formylation; non-rearranged oximes appear in Table XII.

Table XVIII has been subdivided according to the number of component rings, with monocyclic systems first (XVIII A), and polycyclic systems second (XVIII B). Within each ring classification, rings are arranged by size, and within each group by the increasing number of component carbon atoms.

Compounds with multiple functionality, for example ketoesters, are listed in only one Table. Such compounds are assigned to the Table which best appears to reflect their chemistry, but readers are advised to search both Tables in such cases.

^a The yield given is that of the product isolated as the cupric salt.

^b The authors repeated the work detailed in reference #83 where the yield was reported as 20%. They did not report a yield for this reaction in reference #84.

^c This reaction was carried out at rt.

^d The ratio of *E* to *Z* isomers in the crude mixture is 6:4.

^e Sixty percent of the starting ketone was recovered.

CUMULATIVE CHAPTER TITLES BY VOLUME

Volume 1 (1942)

1. **The Reformatsky Reaction:** Ralph L. Shriner
2. **The Arndt-Eistert Reaction:** W. E. Bachmann and W. S. Struve
3. **Chloromethylation of Aromatic Compounds:** Reynold C. Fuson and C. H. McKeever
4. **The Amination of Heterocyclic Bases by Alkali Amides:** Marlin T. Leffler
5. **The Bucherer Reaction:** Nathan L. Drake
6. **The Elbs Reaction:** Louis F. Fieser
7. **The Clemmensen Reduction:** Elmore L. Martin
8. **The Perkin Reaction and Related Reactions:** John R. Johnson
9. **The Acetoacetic Ester Condensation and Certain Related Reactions:** Charles R. Hauser and Boyd E. Hudson, Jr.
10. **The Mannich Reaction:** F. F. Blicke
11. **The Fries Reaction:** A. H. Blatt
12. **The Jacobson Reaction:** Lee Irvin Smith

Volume 2 (1944)

1. **The Claisen Rearrangement:** D. Stanley Tarbell
2. **The Preparation of Aliphatic Fluorine Compounds:** Albert L. Henne
3. **The Cannizzaro Reaction:** T. A. Geissman
4. **The Formation of Cyclic Ketones by Intramolecular Acylation:** William S. Johnson
5. **Reduction with Aluminum Alkoxides (The Meerwein-Ponndorf-Verley Reduction):** A. L. Wilds

6. **The Preparation of Unsymmetrical Biaryls by the Diazo Reaction and the Nitrosoacetylamine Reaction:** Werner E. Bachmann and Roger A. Hoffman
7. **Replacement of the Aromatic Primary Amino Group by Hydrogen:** Nathan Kornblum
8. **Periodic Acid Oxidation:** Ernest L. Jackson
9. **The Resolution of Alcohols:** A. W. Ingersoll
10. **The Preparation of Aromatic Arsonic and Arsinic Acids by the Bart, Béchamp, and Rosenmund Reactions:** Cliff S. Hamilton and Jack F. Morgan

Volume 3 (1946)

1. **The Alkylation of Aromatic Compounds by the Friedel-Crafts Method:** Charles C. Price
2. **The Willgerodt Reaction:** Marvin Carmack and M. A. Spielman
3. **Preparation of Ketenes and Ketene Dimers:** W. E. Hanford and John C. Sauer
4. **Direct Sulfonation of Aromatic Hydrocarbons and Their Halogen Derivatives:** C. M. Suter and Arthur W. Weston
5. **Azlactones:** H. E. Carter
6. **Substitution and Addition Reactions of Thiocyanogen:** John L. Wood
7. **The Hofmann Reaction:** Everett L. Wallis and John F. Lane
8. **The Schmidt Reaction:** Hans Wolff
9. **The Curtius Reaction:** Peter A. S. Smith

Volume 4 (1948)

1. **The Diels-Alder Reaction with Maleic Anhydride:** Milton C. Kloetzel
2. **The Diels-Alder Reaction: Ethylenic and Acetylenic Dienophiles:** H. L. Holmes
3. **The Preparation of Amines by Reductive Alkylation:** William S. Emerson
4. **The Acyloins:** S. M. McElvain
5. **The Synthesis of Benzoin:** Walter S. Ide and Johannes S. Buck
6. **Synthesis of Benzoquinones by Oxidation:** James Cason
7. **The Rosenmund Reduction of Acid Chlorides to Aldehydes:** Erich Mosettig and Ralph Mozingo
8. **The Wolff-Kishner Reduction:** David Todd

Volume 5 (1949)

1. **The Synthesis of Acetylenes:** Thomas L. Jacobs
2. **Cyanoethylation:** Herman L. Bruson
3. **The Diels-Alder Reaction: Quinones and Other Cyclenones:** Lewis L. Butz and Anton W. Rytina
4. **Preparation of Aromatic Fluorine Compounds from Diazonium Fluoborates: The Schiemann Reaction:** Arthur Roe
5. **The Friedel and Crafts Reaction with Aliphatic Dibasic Acid Anhydrides:** Ernst Berliner
6. **The Gattermann-Koch Reaction:** Nathan N. Crouse
7. **The Leuckart Reaction:** Maurice L. Moore
8. **Selenium Dioxide Oxidation:** Norman Rabjohn
9. **The Hoesch Synthesis:** Paul E. Spoerri and Adrien S. DuBois
10. **The Darzens Glycidic Ester Condensation:** Melvin S. Newman and Barney J. Magerlein

Volume 6 (1951)

1. **The Stobbe Condensation:** William S. Johnson and Guido H. Daub
2. **The Preparation of 3,4-Dihydroisoquinolines and Related Compounds by the Bischler-Napieralski Reaction:** Wilson M. Whaley and Tutucorin R. Govindachari
3. **The Pictet-Spengler Synthesis of Tetrahydroisoquinolines and Related Compounds:** Wilson M. Whaley and Tutucorin R. Govindachari
4. **The Synthesis of Isoquinolines by the Pomeranz-Fritsch Reaction:** Walter J. Gensler
5. **The Oppenauer Oxidation:** Carl Djerassi
6. **The Synthesis of Phosphonic and Phosphinic Acids:** Gennady M. Kosolapoff
7. **The Halogen-Metal Interconversion Reaction with Organolithium Compounds:** Reuben G. Jones and Henry Gilman
8. **The Preparation of Thiazoles:** Richard H. Wiley, D. C. England, and Lyell C. Behr
9. **The Preparation of Thiophenes and Tetrahydrothiophenes:** Donald E. Wolf and Karl Folkers
10. **Reductions by Lithium Aluminum Hydride:** Weldon G. Brown

Volume 7 (1953)

1. **The Pechmann Reaction:** Suresh Sethna and Ragini Phadke
2. **The Skraup Synthesis of Quinolines:** R. H. F. Manske and Marshall Kulka
3. **Carbon-Carbon Alkylations with Amines and Ammonium Salts:**
James H. Brewster and Ernest L. Eliel
4. **The von Braun Cyanogen Bromide Reaction:** Howard A. Hageman
5. **Hydrogenolysis of Benzyl Groups Attached to Oxygen, Nitrogen, or Sulfur:**
Walter H. Hartung and Robert Simonoff
6. **The Nitrosation of Aliphatic Carbon Atoms:** Oscar Touster
7. **Epoxidation and Hydroxylation of Ethylenic Compounds with Organic Peracids:** Daniel Swern

Volume 8 (1954)

1. **Catalytic Hydrogenation of Esters to Alcohols:** Homer Adkins
2. **The Synthesis of Ketones from Acid Halides and Organometallic Compounds of Magnesium, Zinc, and Cadmium:** David A. Shirley
3. **The Acylation of Ketones to Form β -Diketones or β -Keto Aldehydes:**
Charles R. Hauser, Frederic W. Swamer, and Joe T. Adams
4. **The Sommelet Reaction:** S. J. Aagyal
5. **The Synthesis of Aldehydes from Carboxylic Acids:** Erich Mosettig
6. **The Metalation Reaction with Organolithium Compounds:** Henry Gilman and John W. Morton, Jr.
7. **β -Lactones:** Harold E. Zaugg
8. **The Reaction of Diazomethane and Its Derivatives with Aldehydes and Ketones:** C. David Gutsche

Volume 9 (1957)

1. **The Cleavage of Non-enolizable Ketones with Sodium Amide:** K. E. Hamlin and Arthur W. Weston
2. **The Gattermann Synthesis of Aldehydes:** William E. Truce
3. **The Baeyer-Villiger Oxidation of Aldehydes and Ketones:** C. H. Hassall
4. **The Alkylation of Esters and Nitriles:** Arthur C. Cope, H. L. Holmes, and Herbert O. House

5. **The Reaction of Halogens with Silver Salts of Carboxylic Acids:** C. V. Wilson
6. **The Synthesis of β -Lactams:** John C. Sheehan and Elias J. Corey
7. **The Pschorr Synthesis and Related Diazonium Ring Closure Reactions:**
DeLos F. DeTar

Volume 10 (1959)

1. **The Coupling of Diazonium Salts with Aliphatic Carbon Atoms:**
Stanley J. Parmerter
2. **The Japp-Klingemann Reaction:** Robert R. Phillips
3. **The Michael Reaction:** Ernst D. Bergmann, David Ginsburg, and Raphael Pappo

Volume 11 (1960)

1. **The Beckmann Rearrangement:** L. Guy Donaruma and Walter Z. Heldt
2. **The Demjanov and Tiffeneau-Demjanov Ring Expansions:** Peter A. S. Smith and Donald R. Baer
3. **Arylation of Unsaturated Compounds by Diazonium Salts:**
Christian S. Rondestvedt, Jr.
4. **The Favorskii Rearrangement of Haloketones:** Andrew S. Kende
5. **Olefins from Amines: The Hofmann Elimination Reaction and Amine Oxide Pyrolysis:** Arthur C. Cope and Elmer R. Trumbull

Volume 12 (1962)

1. **Cyclobutane Derivatives from Thermal Cycloaddition Reactions:** John D. Roberts and Clay M. Sharts
2. **The Preparation of Olefins by the Pyrolysis of Xanthates. The Chugaev Reaction:** Harold R. Nace
3. **The Synthesis of Aliphatic and Alicyclic Nitro Compounds:** Nathan Kornblum
4. **Synthesis of Peptides with Mixed Anhydrides:** Noel F. Albertson
5. **Desulfurization with Raney Nickel:** George R. Pettit and Eugene E. van Tamelen

Volume 13 (1963)

1. **Hydration of Olefins, Dienes, and Acetylenes via Hydroboration:** George Zweifel and Herbert C. Brown

2. **Halocyclopropanes from Halocarbenes:** William E. Parham and Edward E. Schweizer
3. **Free Radical Addition to Olefins to Form Carbon-Carbon Bonds:** Cheves Walling and Earl S. Huyser
4. **Formation of Carbon-Heteroatom Bonds by Free Radical Chain Additions to Carbon-Carbon Multiple Bonds:** F. W. Stacey and J. F. Harris, Jr.

Volume 14 (1965)

1. **The Chapman Rearrangement:** J. W. Schulenberg and S. Archer
2. **α -Amidoalkylations at Carbon:** Harold E. Zaugg and William B. Martin
3. **The Wittig Reaction:** Adalbert Maercker

Volume 15 (1967)

1. **The Dieckmann Condensation:** John P. Schaefer and Jordan J. Bloomfield
2. **The Knoevenagel Condensation:** G. Jones

Volume 16 (1968)

1. **The Aldol Condensation:** Arnold T. Nielsen and William J. Houlihan

Volume 17 (1969)

1. **The Synthesis of Substituted Ferrocenes and Other π -Cyclopentadienyl-Transition Metal Compounds:** Donald E. Bublitz and Kenneth L. Rinehart, Jr.
2. **The γ -Alkylation and γ -Arylation of Dianions of β -Dicarbonyl Compounds:** Thomas M. Harris and Constance M. Harris
3. **The Ritter Reaction:** L. I. Krimen and Donald J. Cota

Volume 18 (1970)

1. **Preparation of Ketones from the Reaction of Organolithium Reagents with Carboxylic Acids:** Margaret J. Jorgenson
2. **The Smiles and Related Rearrangements of Aromatic Systems:** W. E. Truce, Eunice M. Kreider, and William W. Brand
3. **The Reactions of Diazoacetic Esters with Alkenes, Alkynes, Heterocyclic, and Aromatic Compounds:** Vinod Dave and E. W. Warnhoff
4. **The Base-Promoted Rearrangements of Quaternary Ammonium Salts:** Stanley H. Pine

Volume 19 (1972)

1. **Conjugate Addition Reactions of Organocopper Reagents:** Gary H. Posner
2. **Formation of Carbon-Carbon Bonds via π -Allylnickel Compounds:** Martin F. Semmelhack
3. **The Thiele-Winter Acetoxylation of Quinones:** J. F. W. McOmie and J. M. Blatchly
4. **Oxidative Decarboxylation of Acids by Lead Tetraacetate:** Roger A. Sheldon and Jay K. Kochi

Volume 20 (1973)

1. **Cyclopropanes from Unsaturated Compounds, Methylene Iodide, and Zinc-Copper Couple:** H. E. Simmons, T. L. Cairns, Susan A. Vladuchick, and Connie M. Hoiness
2. **Sensitized Photooxygenation of Olefins:** R. W. Denny and A. Nickon
3. **The Synthesis of 5-Hydroxyindoles by the Nenitzescu Reaction:** George R. Allen, Jr.
4. **The Zinin Reaction of Nitroarenes:** H. K. Porter

Volume 21 (1974)

1. **Fluorination with Sulfur Tetrafluoride:** G. A. Boswell, Jr., W. C. Ripka, R. M. Scribner, and C. W. Tullock
2. **Modern Methods to Prepare Monofluoroaliphatic Compounds:** Clay M. Sharts and William A. Sheppard

Volume 22 (1975)

1. **The Claisen and Cope Rearrangements:** Sara Jane Rhoads and N. Rebecca Raulins
2. **Substitution Reactions Using Organocopper Reagents:** Gary H. Posner
3. **Clemmensen Reduction of Ketones in Anhydrous Organic Solvents:** E. Vedejs
4. **The Reformatsky Reaction:** Michael W. Rathke

Volume 23 (1976)

1. **Reduction and Related Reactions of α,β -Unsaturated Compounds with Metals in Liquid Ammonia:** Drury Caine
2. **The Acyloin Condensation:** Jordan J. Bloomfield, Dennis C. Owsley, and Janice M. Nelke
3. **Alkenes from Tosylhydrazones:** Robert H. Shapiro

Volume 24 (1976)

1. **Homogeneous Hydrogenation Catalysts in Organic Solvents:** Arthur J. Birch and David H. Williamson
2. **Ester Cleavages via S_N2-Type Dealkylation:** John E. McMurry
3. **Arylation of Unsaturated Compounds by Diazonium Salts (The Meerwein Arylation Reaction):** Christian S. Rondestvedt, Jr.
4. **Selenium Dioxide Oxidation:** Norman Rabjohn

Volume 25 (1977)

1. **The Ramberg-Bäcklund Rearrangement:** Leo A. Paquette
2. **Synthetic Applications of Phosphoryl-Stabilized Anions:** William S. Wadsworth, Jr.
3. **Hydrocyanation of Conjugated Carbonyl Compounds:** Wataru Nagata and Mitsuru Yoshioka

Volume 26 (1979)

1. **Heteroatom-Facilitated Lithiations:** Heinz W. Gschwend and Herman R. Rodriguez
2. **Intramolecular Reactions of Diazocarbonyl Compounds:** Steven D. Burke and Paul A. Grieco

Volume 27 (1982)

1. **Allylic and Benzylic Carbanions Substituted by Heteroatoms:** Jean-François Biellmann and Jean-Bernard Ducep
2. **Palladium-Catalyzed Vinylation of Organic Halides:** Richard F. Heck

Volume 28 (1982)

1. **The Reimer-Tiemann Reaction:** Hans Wynberg and Egbert W. Meijer
2. **The Friedländer Synthesis of Quinolines:** Chia-Chung Cheng and Shou-Jen Yan
3. **The Directed Aldol Reaction:** Teruaki Mukaiyama

Volume 29 (1983)

1. **Replacement of Alcoholic Hydroxy Groups by Halogens and Other Nucleophiles via Oxyphosphonium Intermediates:** Bertrand R. Castro

2. **Reductive Dehalogenation of Polyhalo Ketones with Low-Valent Metals and Related Reducing Agents:** Ryoji Noyori and Yoshihiro Hayakawa
3. **Base-Promoted Isomerizations of Epoxides:** Jack K. Crandall and Marcel Apparau

Volume 30 (1984)

1. **Photocyclization of Stilbenes and Related Molecules:** Frank B. Mallory and Clelia W. Mallory
2. **Olefin Synthesis via Deoxygenation of Vicinal Diols:** Eric Block

Volume 31 (1984)

1. **Addition and Substitution Reactions of Nitrile-Stabilized Carbanions:** Siméon Arseniyadis, Keith S. Kyler, and David S. Watt

Volume 32 (1984)

1. **The Intramolecular Diels-Alder Reaction:** Engelbert Ciganek
2. **Synthesis Using Alkyne-Derived Alkenyl- and Alkynylaluminum Compounds:** George Zweifel and Joseph A. Miller

Volume 33 (1985)

1. **Formation of Carbon-Carbon and Carbon-Heteroatom Bonds via Organoboranes and Organoborates:** Ei-Ichi Negishi and Michael J. Idacavage
2. **The Vinylcyclopropane-Cyclopentene Rearrangement:** Tomáš Hudlický, Toni M. Kutchan, and Saiyid M. Naqvi

Volume 34 (1985)

1. **Reductions by Metal Alkoxyaluminum Hydrides:** Jaroslav Málek
2. **Fluorination by Sulfur Tetrafluoride:** Chia-Lin J. Wang

Volume 35 (1988)

1. **The Beckmann Reactions: Rearrangements, Elimination-Additions, Fragmentations, and Rearrangement-Cyclizations:** Robert E. Gawley
2. **The Persulfate Oxidation of Phenols and Arylamines (The Elbs and the Boyland-Sims Oxidations):** E. J. Behrman
3. **Fluorination with Diethylaminosulfur Trifluoride and Related Aminofluorosulfuranes:** Miloš Hudlický

Volume 36 (1988)

1. **The [3 + 2] Nitrone-Olefin Cycloaddition Reaction:** Pat N. Confalone and Edward M. Huic
2. **Phosphorus Addition at sp^2 Carbon:** Robert Engel
3. **Reduction by Metal Alkoxyaluminum Hydrides. Part II. Carboxylic Acids and Derivatives, Nitrogen Compounds, and Sulfur Compounds:** Jaroslav Málek

Volume 37 (1989)

1. **Chiral Synthons by Ester Hydrolysis Catalyzed by Pig Liver Esterase:** Masaji Ohno and Masami Otsuka
2. **The Electrophilic Substitution of Allylsilanes and Vinylsilanes:** Ian Fleming, Jacques Dunoguès, and Roger Smithers

Volume 38 (1990)

1. **The Peterson Olefination Reaction:** David J. Ager
2. **Tandem Vicinal Difunctionalization: β -Addition to α,β -Unsaturated Carbonyl Substrates Followed by α -Functionalization:** Marc J. Chapdelaine and Martin Hulce
3. **The Nef Reaction:** Harold W. Pinnick

Volume 39 (1990)

1. **Lithioalkenes from Arenesulfonylhydrazones:** A. Richard Chamberlin and Steven H. Bloom
2. **The Polonovski Reaction:** David Grierson
3. **Oxidation of Alcohols to Carbonyl Compounds via Alkoxy-sulfonium Ylides: The Moffatt, Swern, and Related Oxidations:** Thomas T. Tidwell

Volume 40 (1991)

1. **The Pauson-Khand Cycloaddition Reaction for Synthesis of Cyclopentenones:** Neil E. Schore
2. **Reduction with Diimide:** Daniel J. Pasto and Richard T. Taylor
3. **The Pummerer Reaction of Sulfinyl Compounds:** Ottorino DeLucchi, Umberto Miotti, and Giorgio Modena
4. **The Catalyzed Nucleophilic Addition of Aldehydes to Electrophilic Double Bonds:** Hermann Stetter and Heinrich Kuhlmann

Volume 41 (1992)

1. **Divinylcyclopropane-Cycloheptadiene Rearrangement:** Tomáš Hudlický, Rulin Fan, Josephine W. Reed, and Kumar G. Gadamasetti
2. **Organocopper Reagents: Substitution, Conjugate Addition, Carbo/Metallocupration, and Other Reactions:** Bruce H. Lipshutz and Saumitra Sengupta

Volume 42 (1992)

1. **The Birch Reduction of Aromatic Compounds:** Peter W. Rabideau and Zbigniew Marcinow
2. **The Mitsunobu Reaction:** David L. Hughes

Volume 43 (1993)

1. **Carbonyl Methylenation and Alkylidenation Using Titanium-Based Reagents:** Stanley H. Pine
2. **Anion-Assisted Sigmatropic Rearrangements:** Stephen R. Wilson
3. **The Baeyer-Villiger Oxidation of Ketones and Aldehydes:** Grant R. Krow

Volume 44 (1993)

1. **Preparation of α,β -Unsaturated Carbonyl Compounds and Nitriles by Selenoxide Elimination:** Hans J. Reich and Susan Wollowitz
2. **Enone Olefin [2 + 2] Photochemical Cyclizations:** Michael T. Crimmins and Tracy L. Reinhold

Volume 45 (1994)

1. **The Nazarov Cyclization:** Karl L. Habermas, Scott E. Denmark, and Todd K. Jones
2. **Ketene Cycloadditions:** John A. Hyatt and Peter W. Raynolds

Volume 46 (1994)

1. **Tin(II) Enolates in the Aldol, Michael, and Related Reactions:** Teruaki Mukaiyama and Shū Kobayashi
2. **The [2,3]-Wittig Reaction:** Takeshi Nakai and Koichi Mikami
3. **Reductions with Samarium(II) Iodide:** Gary A. Molander

Volume 47 (1995)

1. **Lateral Lithiation Reactions Promoted by Heteroatomic Substituents:** Robin D. Clark and Alam Jahangir
2. **The Intramolecular Michael Reaction:** R. Daniel Little, Mohammad R. Masjedizadeh, Olof Wallquist (in part), and Jim I. McLoughlin (in part)

Volume 48 (1996)

1. **Asymmetric Epoxidation of Allylic Alcohols: The Katsuki–Sharpless Epoxidation Reaction:** Tsutomu Katsuki and Victor S. Martin
2. **Radical Cyclization Reactions:** B. Giese, B. Kopping, T. Göbel, J. Dickhaut, G. Thoma, K. J. Kulicke, and F. Trach

Volume 49 (1997)

1. **The Vilsmeier Reaction of Fully Conjugated Carbocycles and Heterocycles:** Gurnos Jones and Stephen P. Stanforth
2. **[6 + 4] Cycloaddition Reactions:** James H. Rigby
3. **Carbon–Carbon Bond-Forming Reactions Promoted by Trivalent Manganese:** Gagik G. Melikyan

Volume 50 (1997)

1. **The Stille Reaction:** Vittorio Farina, Venkat Krishnamurthy, and William J. Scott

Volume 51 (1997)

1. **Asymmetric Aldol Reactions Using Boron Enolates:** Cameron J. Cowden and Ian Paterson
2. **The Catalyzed α -Hydroxylation and α -Aminoalkylation of Activated Olefins (The Morita–Baylis–Hillman Reaction):** Engelbert Ciganek
3. **[4 + 3] Cycloaddition Reactions:** James H. Rigby and F. Christopher Pigge

Volume 52 (1998)

1. **The Retro–Diels–Alder Reaction. Part I. C–C Dienophiles:** Bruce Rickborn
2. **Enantioselective Reduction of Ketones:** Shinichi Itsuno

Volume 53 (1998)

1. **The Oxidation of Alcohols by Modified Oxochromium(VI)-Amine Reagents:** Frederick A. Luzzio
2. **The Retro–Diels–Alder Reaction. Part II. Dienophiles with One or More Heteroatoms:** Bruce Rickborn

Volume 54 (1999)

1. **Aromatic Substitution by the $S_{RN}1$ Reaction:** Roberto Rossi, Adriana B. Pierini, and Ana N. Santiago
2. **Oxidation of Carbonyl Compounds with Organohypervalent Iodine Reagents:** Robert M. Moriarty and Om Prakash

Volume 55 (1999)

1. **Synthesis of Nucleosides:** Helmut Vorbrüggen and Carmen Ruh-Pohlentz
