

formed directly from 4 and 2 whereas the  $\text{PMe}_3$  analogue to 5 was prepared by Stone et al. in a two-step process by reacting 4 with a source of  $\text{Pt}(\text{PMe}_3)_2^0$  followed by protonation of the isolated  $\mu$ -alkylidyne cluster with  $\text{HBF}_4 \cdot \text{Et}_2\text{O}$ .<sup>8</sup>

The results of eq 1 and 2 indicate that 2 (and possibly related complexes) might be generally useful reagents for preparing clusters from compounds containing unsaturated bonds at appropriate locations by either formal insertion or proton transfer reactions. These reactions complement the recent extensive cluster chemistry of Stone<sup>10</sup> with the important difference that in this method the "addition" of the Pt-H bond to the reactant complex changes the identity of the eventual bridging ligand. A study of the reactions of 2 (and related species) with other alkylidyne complexes and other compounds containing unsaturated bonds is being pursued.

### Stereoselective Additions to the Alkoxy-carbene Cations $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\text{CO})(\text{PPh}_3)(=\text{CROME})]^+$ (R = H, Et)

Gordon J. Baird, Stephen G. Davies,\* and Timothy R. Maberly

Received June 26, 1984

**Summary:** Nucleophilic addition reactions to the cations  $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\text{CO})(\text{PPh}_3)(=\text{CROME})]^+$  (R = H, Et) are highly stereoselective. The product diastereoisomers  $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\text{CO})(\text{PPh}_3)(\text{CH}(\text{R})\text{OMe})]$  undergo epimerization in methanol prior to formation of (E)- $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\text{CO})(\text{PPh}_3)(\text{CH}=\text{CHMe})]$ .

We have recently presented a series of guidelines concerning the reactivity of ligands bound to the  $(\eta^5\text{-C}_5\text{H}_5)\text{-Fe}(\text{CO})(\text{PPh}_3)$  moiety.<sup>1</sup> In particular, it was predicted, by analogy with the acyl complexes 1, that the alkoxy-carbene cations 2 should exist in the anti (O-O) conformation and that high stereoselectivities should be seen in their reactions with nucleophiles.

Several reports of the hydride reductions of cations 2 have appeared with little stereoselectivity apparently being observed.<sup>2,3</sup> More surprising was the reported observation that borohydride in the presence of methoxide smoothly

reduced 3 without deprotonation to the corresponding methoxyvinyl complexes<sup>3</sup> especially since we have recently found that this deprotonation is extremely facile.<sup>4</sup> We report here a reexamination of the reduction of complex 3 together with a more extensive description of its reactivity and reduction products.

Treatment of the acyl complex 4 with trimethyloxonium tetrafluoroborate generated cation 3.<sup>5</sup> An X-ray crystallographic analysis of 3<sup>6</sup> showed that as expected<sup>1</sup> the oxygens were anti and one face of the alkoxy-carbene ligand was shielded by the proximate phenyl group of the triphenylphosphine ligand. Treatment of 3 with sodium methoxide quantitatively generated the methoxyvinyl complex 5 (E:Z = 1:100).

In our hands reduction of cation 3 with a variety of hydride reagents (e.g.,  $\text{LiAlH}_4$ ,  $\text{NaBH}_4$ ) in tetrahydrofuran is very stereoselective with the two diastereoisomers 6 and 7 being produced in the ratio 15:1 ( $\text{NaBH}_4$ ,  $-100^\circ\text{C}$ ). The ratio of 6:7 dropped to 12:1 when this reduction was performed at  $-78^\circ\text{C}$ . The major diastereoisomer is assigned as 6 on the assumption that hydride adds to the unhindered face of the carbene 3 in the anti (O-O) conformation.<sup>1</sup> Diastereoisomer 6 could be isolated pure by crystallization.<sup>7</sup> With use of the literature procedure<sup>3</sup> of adding a dichloromethane solution of 3 to  $\text{NaBH}_4/\text{NaOMe}$  in methanol, a mixture of the reduced products 6 and 7 together with the deprotonated product 5 was obtained in the ratio 8.5:1:4.5, respectively (lit.<sup>3</sup> 6:7 = 3:1). Hindered

reducing agents such as  $K[s\text{-Bu}_3\text{BH}]$  gave only the deprotonated product 5.<sup>7</sup>

Hydride abstraction from the methoxymethyl complex 8 with the trityl cation generated the carbene cation 9.<sup>8</sup> Treatment of 9 with ethyllithium in dichloromethane at  $-78^\circ\text{C}$  again generated the diastereoisomers 6 and 7. This time, as expected, 7 was by far the major product (7:6 > 30:1) consistent with attack onto the unhindered face of 9 in the anti (O-O) conformation. Recrystallization gave pure 7.<sup>7</sup>

Methanol-dichloromethane (1:2) solutions of 6 or 7 at  $20^\circ\text{C}$  undergo epimerization, presumably via reversible loss of methoxide to give the carbene cation 10. In the presence of methanol-*d*<sub>4</sub> incorporation of  $\text{CD}_3\text{O}$  into 6 and 7 was observed ( $\text{CD}_2\text{Cl}_2/\text{CD}_3\text{OD}$ , 2:1;  $20^\circ\text{C}$ ; 90% incorporation after 24 h). In methanol solution 6 and 7 slowly undergo methanol loss to generate the stable (*E*)-vinyl complex 11.

## Unprecedented Alkyl Migration in an Iron(II) Alkylidene<sup>1</sup>

Robert S. Bly\* and Gary S. Silverman

Department of Chemistry, University of South Carolina  
Columbia, South Carolina 29208

Received September 5, 1984

**Summary:** Protonation of  $(\eta^5\text{-C}_5\text{H}_5)(\text{CO})_2\text{FeCR}(1\text{-norbornyl})\text{OC}_2\text{H}_5$  ( $R = \text{H}$  or  $\text{D}$ ) with  $\text{HBF}_4$  provides  $[(\eta^5\text{-C}_5\text{H}_5)(\text{CO})_2\text{Fe}(\text{exo-}\eta^2\text{-1-R-bicyclo[3.2.1]oct-2-ene})]^+\text{BF}_4^-$  ( $R = \text{H}$  or  $\text{D}$ ) in nearly quantitative yield. No  $[(\eta^5\text{-C}_5\text{H}_5)(\text{CO})_2\text{Fe}(\eta^2\text{-bicyclo[2.2.2]oct-2-ene})]^+\text{BF}_4^-$  is formed. This regioselective reaction is thought first to form an  $[(\eta^5\text{-C}_5\text{H}_5)(\text{CO})_2\text{Fe}(1\text{-norbornylmethylidene})]^+$ , which undergoes an unprecedented ring enlargement to a  $[(\eta^5\text{-C}_5\text{H}_5)(\text{CO})_2\text{Fe}(\eta^2\text{-bicyclooct-1-ene})]^+$  and then rearranges to the final product.

In an effort to form and trap an unstable<sup>2</sup> bridgehead olefin as a  $\pi$ -complex, we have generated and examined the reaction of  $[\text{Fp}(1\text{-norbornylmethylidene})]^+$  [ $\text{A}$ ,  $\text{Fp} = (\eta^5\text{-C}_5\text{H}_5)(\text{CO})_2\text{Fe}$ ] in acid solution.

Alkylation<sup>3</sup> of the Fp-acyl, 1,<sup>4</sup> with  $\text{Et}_3\text{O}^+\text{BF}_4^-$  in  $\text{CH}_2\text{Cl}_2$  at  $25^\circ\text{C}$  gives the yellow ethoxycarbene salt 2<sup>5</sup> in >90% yield. Reduction of 2 in  $\text{CH}_2\text{Cl}_2$  at  $-78^\circ\text{C}$  with a 1 M solution of  $\text{LiEt}_3\text{BH}$  in  $\text{THF}$ <sup>6</sup> produces the ethoxyalkyl complex 3<sup>7</sup> as a yellow oil in 65% yield. Protonation of 3 in  $\text{CH}_2\text{Cl}_2$  at  $25^\circ\text{C}$  with a slight excess of  $\text{HBF}_4$  in  $\text{Ac}_2\text{O}/\text{HOAc}/\text{CH}_2\text{Cl}_2$ ,<sup>8</sup> concentration, and dilution with  $\text{Et}_2\text{O}$  gives an essentially quantitative yield of a yellow, crystalline  $\text{Fp}(\eta^2\text{-bicyclooctene})^+\text{BF}_4^-$  identical with that<sup>9</sup>
