

**Figure 5.** Overall mechanism for the oxidation and reduction of  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$ . Numbers 1-4 correspond to processes in the cyclic voltammograms illustrated in Figure 1. The possible solvation of  $[(\text{TPP})\text{Ir}]^+$  is omitted for clarity.

**Overall Reaction Scheme for  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$ .** The overall reaction scheme of  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  in PhCN and  $\text{CH}_2\text{Cl}_2$  is summarized in Figure 5.  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  can undergo two consecutive reductions at the porphyrin  $\pi$ -ring system to form an anion radical and a dianion. This electron-transfer mechanism is supported by the electrochemical and spectroelectrochemical data as well as by the ESR spectra recorded after bulk solution electrolysis.

The first oxidation of  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  is followed by a chemical reaction to generate  $[(\text{TPP})\text{Ir}]^+\text{ClO}_4^-$  in PhCN, 0.2 M TBAP. Similar types of reactions have been reported for  $(\text{TPP})[\text{Rh}(\text{CO})_2]_2^{17}$  which, upon oxidation, generates a transient  $\text{Rh}^{\text{II}}-\text{Rh}^{\text{I}}$  complex followed by an intramolecular electron transfer to form  $[(\text{TPP})\text{Rh}]^+\text{ClO}_4^-$  and elemental rhodium metal. The formation of  $[(\text{TPP})\text{Ir}]^+\text{ClO}_4^-$  following the one-electron oxidation of

$(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  would also require the transfer of a second electron, presumably from the second iridium atom. However, iridium metal was not clearly isolated in the present study, and positive identification of the second electron source has not been made.

In summary, the electrochemical properties of  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  are almost identical with the properties of  $(\text{TPP})[\text{Rh}(\text{CO})_2]_2$ . The first reduction of both binuclear complexes reversibly occurs at the porphyrin  $\pi$ -ring system. The values of  $E_{1/2}$  are similar and occur at  $-0.99$  V for  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  and  $-1.04$  V for  $(\text{TPP})[\text{Rh}(\text{CO})_2]_2$  in benzonitrile. The first oxidation of both binuclear complexes is irreversible and occurs at  $E_p = 0.92$  V for  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  and  $E_p = 0.84$  V for  $(\text{TPP})[\text{Rh}(\text{CO})_2]_2$  in benzonitrile at a scan rate of  $0.1$  V/s.<sup>17</sup> The electrooxidation of each compound involves the overall conversion of a metal(I) to a metal(III) ion and the ultimate formation of  $[(\text{P})\text{M}]^+$ . However, unlike  $(\text{TPP})[\text{Rh}(\text{CO})_2]_2$  which can be reversibly oxidized at low temperature or fast scan rates, the chemical reaction or reactions following electron abstraction from  $(\text{TPP})[\text{Ir}(\text{CO})_3]_2$  are extremely rapid and in no case could reversible electrooxidations be obtained.

## Kinetic and Thermodynamic Acidity of Hydrido Transition-Metal Complexes. 5. Sensitivity of Thermodynamic Acidity to Ligand Variation and Hydride Bonding Mode

Sigríður S. Kristjánssdóttir, Anne E. Moody, Rolf T. Weberg, and Jack R. Norton\*

Department of Chemistry, Colorado State University, Fort Collins, Colorado 80523

Received December 21, 1987

The  $pK_a$  values of  $\text{CpRe}(\text{CO})_2\text{H}_2$ ,  $(\eta^3-\text{C}_6\text{H}_5)\text{Mn}(\text{CO})_3$ ,  $(\eta^6-\text{C}_6\text{H}_6)\text{Mn}(\text{CO})_2\text{H}$ ,  $\text{HMn}(\text{CO})_4(\text{PPh}_3)$ ,  $\text{HMn}(\text{CO})_4(\text{PEtPh}_2)$ ,  $(\mu-\text{H})_2\text{Fe}_3(\text{CO})_9(\mu_3-\text{P}-t\text{-Bu})$ ,  $(\mu-\text{H})_2\text{Fe}_3(\text{CO})_9(\mu_3-\text{P}-p\text{-C}_6\text{H}_5\text{OCH}_3)$ ,  $(\mu-\text{H})\text{Fe}_3(\text{CO})_9(\mu_3-\text{SC}_6\text{H}_{11})$ ,  $\text{H}_4\text{Ru}_4(\text{CO})_{11}(\text{P}(\text{OCH}_3)_3)$ , and  $\text{H}_4\text{Ru}_4(\text{CO})_{10}(\text{P}(\text{OCH}_3)_3)_2$  have been determined in acetonitrile by IR measurement of the position of deprotonation equilibria with various nitrogen bases and sodium phenolate. The acidity of transition-metal hydrides appears more sensitive to the nature of the ancillary ligands than to the identity of the metal center.

We have reported the thermodynamic acidity of common mononuclear transition-metal hydrides in acetonitrile.<sup>1</sup> These results have enabled us to quantify periodic trends and some substituent effects. Our work has been carried out in acetonitrile for several reasons: it dissolves most metal hydrides without decomposition and solvates cations effectively; it minimizes ion pairing; and, as it is both a weak acid and a weak base, a large range of  $pK_a$

values can be measured in it.

We have now extended our initial studies to compounds containing other types of hydride ligands, e.g., to agostic and edge-bridging hydrides. We have also investigated the sensitivity of hydride  $pK_a$  values to small changes in the nature of ancillary phosphine ligands.

We have examined the edge-bridging hydrides in the  $\text{H}_4\text{Ru}_4(\text{CO})_{12-x}(\text{P}(\text{OCH}_3)_3)_x$  of tetranuclear ruthenium hydride clusters because Pearson and Ford<sup>2</sup> had previously studied their thermodynamic and kinetic acidities in

methanol solution and we wanted acetonitrile values with which to compare their results. Finally, we have measured the  $pK_a$  of  $CpRe(CO)_2H_2$  in acetonitrile; in 1984 Bursten<sup>3</sup> had predicted that such seven-coordinate complexes would be more acidic than their six-coordinate analogues.

### Experimental Section

**General Data.** All manipulations were performed under an inert atmosphere ( $N_2$ ) using high vacuum line, Schlenk, or inert-atmosphere box techniques. Acetonitrile was purified by a combination of steps that our previous work had shown were effective:<sup>1</sup> it was distilled from  $CuSO_4$  and then from alkaline  $KMnO_4$ ; it was then passed through a column of Woelm N-Super 1 alumina and finally vacuum transferred from  $P_2O_{10}$ . The  $CD_3CN$  used as an NMR solvent was purified by vacuum transfer from  $P_2O_{10}$ . Methanol was dried by reflux over, and distillation from, calcium hydride.

Aniline, pyridine, morpholine, triethylamine, pyrrolidine, and tetramethylguanidine were predried over, and then fractionally distilled from, barium oxide. Sodium phenolate was generated from phenol and sodium hydride in THF.

Infrared spectra were recorded on a Perkin-Elmer PE983 spectrophotometer using 0.01-cm  $CaF_2$  solution cells.  $^1H$  NMR spectra were recorded on either an IBM WP-200-SY or an IBM WP-270-SY spectrometer.

**Materials.** The following compounds were prepared by literature methods:  $CpRe(CO)_2H_2$  (1),<sup>4</sup>  $HfMn(CO)_4(PEtPh_2)_5$ ,  $H_4Ru_4(CO)_{12}$  (7a),<sup>8</sup> and  $[PPN][H_3Ru_4(CO)_{12}]^{7a}$ . Samples of both  $(\eta^3-C_6H_5)_3Mn(CO)_3$  (2)<sup>8</sup> and  $(\eta^6-C_6H_6)Mn(CO)_2H$  (3) were generously provided by M. Brookhart and S. K. Noh. Samples of  $(\mu-H)_2Fe_3(CO)_9(\mu_3-P-C_6H_4OCH_3)$  (4),  $(\mu-H)_2Fe_3(CO)_9(\mu_3-P-t-Bu)$  (5), and  $(\mu-H)Fe_3(CO)_9(\mu_3-S-C_6H_{11})$  (6) were generously provided by G. Huttner.<sup>10</sup>

**Synthesis of  $H_4Ru_4(CO)_{12-x}(P(OCH_3)_3)_x$  ( $x = 1, 2$ ).** The preparation of these compounds was carried out by using a modified form of the reported method.<sup>11</sup>  $H_4Ru_4(CO)_{12}$  (7a, 200–300 mg, 0.27–0.40 mmol) was treated with an equimolar amount of  $P(OCH_3)_3$  (0.03–0.05 mL) in refluxing heptane. The reaction was monitored by IR. When an absorption at  $2097\text{ cm}^{-1}$ , indicating formation of the monosubstituted cluster ( $x = 1$ ), appeared in the IR spectrum (ca. 15 min), the solution was cooled and solvent was removed in vacuo. (Longer reaction times resulted in loss of product and formation of more highly substituted ( $x = 2-4$ ) species.) Products were separated by chromatography on  $SiO_2$ . Elution with hexanes removed starting material; elution with 1:1 hexanes/dichloromethane removed the trimethyl phosphite substituted clusters in order of increasing ligand substitution. The mono- (7b) and disubstituted (7c) products were isolated in pure form in 10–20% yield and identified by comparison of their IR and  $^1H$  NMR spectra with those in the literature.<sup>11</sup>

**Synthesis of  $[(C_6H_5)_3P)_2N][H_3Ru_4(CO)_{11}(P(OCH_3)_3)]$ .** In a typical preparation,  $H_4Ru_4(CO)_{11}(P(OCH_3)_3)$  (7b, 20 mg, 0.02 mmol) was combined with an equimolar amount of sodium phenolate under  $N_2$ . Tetrahydrofuran (10 mL) was introduced by vacuum transfer, and the resulting orange solution was stirred at room temperature for 30 min. An equimolar amount of  $[(C_6H_5)_3P)_2N]Cl$  was added by syringe as a THF solution. After the solution was stirred for 1 h at room temperature, the solvent

was removed in vacuo. The crude product was redissolved in a minimum volume of methylene chloride and precipitated by slow addition of excess heptane at  $0^\circ C$ . The resulting red-orange microcrystalline solid was washed with cold heptane and dried in vacuo to give a variable yield of the product. The observed spectra agreed with those observed during deprotonation studies (see below) of the parent compound:  $^1H$  NMR ( $CD_3CN$ )  $\delta$  7.56 (m, PPN<sup>+</sup>), 3.57 (d,  $P(OCH_3)_3$ ), -17.33 (br s, ( $\mu-H$ )<sub>3</sub>); IR, see Table I; vis ( $CH_3OH$ )  $\lambda_{max}$  343.2 nm; vis ( $CH_2Cl_2$ )  $\lambda_{max}$  345.6 nm.

**Reaction of 7a with  $NaC_8H_{11}N_2O_3$  in  $CH_3OH$ .**  $H_4Ru_4(CO)_{12}$  (7a, 5.5 mg, 0.0074 mmol) and sodium veronate (29.1 mg, 0.14 mmol) were placed in a 25-mL bulb under nitrogen. Dry methanol (3.5 mL) was added by syringe with stirring under nitrogen. Because  $H_4Ru_4(CO)_{12}$  has limited solubility in methanol, the initial solution was a pale yellow slurry. As the reaction progressed, the solution became more homogeneous and darker orange in color. After 2.5 h, the IR spectrum (0.1-mm  $CaF_2$  solution cell under nitrogen) showed the soluble monoanion  $[H_3Ru_4(CO)_{12}]^-$  as the only species present in the homogeneous solution. The IR spectrum was the same as that of the isolated monoanion of 7a in methanol.

**Reaction of 7a in Methanolic Veronal/Veronate Buffer.** A pH 12.7 buffer solution was prepared under nitrogen from a 0.052 M methanol solution of veronal (5,5'-diethylbarbituric acid,  $pK_a = 12.7$  in  $CH_3OH$ <sup>12</sup>) to which was added the appropriate amount of dry sodium methoxide.  $H_4Ru_4(CO)_{12}$  (7a, 11.1 mg, 0.0149 mmol) was placed in a second bulb under nitrogen. The buffer solution (6 mL) was added by syringe to give a yellow slurry. IR monitoring of the solution showed that reaction progressed slowly over 17 h to give a homogeneous orange solution containing only the soluble monoanion  $[H_3Ru_4(CO)_{12}]^-$ .

**Infrared Experiments: Absorptivities.** The absorptivities of all hydride complexes were determined as in our previous work with isolable hydrides.<sup>1</sup> The absorptivities of most anions were determined from solutions in which they were the only absorbing species; these solutions were prepared either from the isolated anions or by the complete deprotonation in situ of the appropriate hydrides. In the case of  $HfMn(\eta^6-C_6H_6)(CO)_2$ , even a large excess of phenoxide did not give complete deprotonation; the difference between the total metal concentration and the concentration of metal hydride observed in the IR experiment was used to determine the anion concentration. The absorptivities of the mononuclear metal hydrides and their deprotonated forms, at the frequencies of their carbonyl stretching vibrations, are found in Table I. For polynuclear hydride complexes whose IR absorptions overlapped with those of the corresponding anions, absorptivities for both the hydride and the anion were measured at the absorption maxima of both species. These are also included in Table I.

**Equilibrium Constants.** The  $pK_a$  values of the hydrides were determined, as in our previous work,<sup>1</sup> by treating solutions of the hydrides with bases which effected partial deprotonation and established equilibria of the type in eq 1.  $[MH]$  and  $[M^-]$  were

determined by IR, using the absorptivities in Table I. For the polynuclear hydrides, whose absorptions overlapped with those of the corresponding anions, absorptions were measured at several absorption maxima for both the hydride and its anion; the concentrations of both species were calculated by an overdetermined least-squares method.  $[B]$  and  $[BH^+]$  were calculated from the total base initially added, after correction for any association of B and  $BH^+$ . The hydride  $pK_a$  was then calculated by using the measured  $pK_{eq}$  and the known  $pK_a$  of the base in acetonitrile (eq 2). The results are shown in Table II.

$$pK_a = pK_{eq} + pK_a(BH^+) \quad (2)$$

### Results and Discussion

The seven-coordinate cyclopentadienyldicarbonyl-rhenium dihydride (1;  $pK_a = 23.0$  in Table II) is only slightly less acidic than the six-coordinate  $HRe(CO)_5$  ( $pK_a$

**Scheme I**

ordination is negated by the effect of the cyclopentadienyl ligand present in 1 and not in HRe(CO)<sub>5</sub>. (Comparison of the previously reported<sup>1c</sup> pK<sub>a</sub> value of CpFe(CO)<sub>2</sub>H with that of H<sub>2</sub>Fe(CO)<sub>4</sub> and that of CpRu(CO)<sub>2</sub>H with that of H<sub>2</sub>Ru(CO)<sub>4</sub> suggests that the presence of cyclopentadienyl ligands decreases the acidity of carbonyl hydrides.)

The pK<sub>a</sub> given for HMn(CO)<sub>4</sub>(PPh<sub>3</sub>) in Table II (20.4) shows that the substitution of PPh<sub>3</sub> for CO in HMn(CO)<sub>5</sub> (pK<sub>a</sub> = 15.1<sup>1c</sup>) decreases its acidity by 5.3 pK<sub>a</sub> units. This effect is comparable to the decrease in acidity upon replacement of CO in HCo(CO)<sub>4</sub> by P(OPh)<sub>3</sub> (3 pK<sub>a</sub> units) or by PPh<sub>3</sub> (7 pK<sub>a</sub> units).<sup>1c</sup> The effect of the further change from triphenylphosphine in HMn(CO)<sub>4</sub>(PPh<sub>3</sub>) (pK<sub>a</sub> = 20.4) to diphenylethylphosphine in HMn(CO)<sub>4</sub>(PEtPh<sub>2</sub>) (pK<sub>a</sub> = 21.6) is a decrease in acidity of 1.2 more pK<sub>a</sub> units. Thus even a small change in the electron-donating ability of the other ligands present results in a measurable change in the acidity of a hydride ligand.

On the basis of the pK<sub>a</sub> values of CpRe(CO)<sub>2</sub>H<sub>2</sub> (pK<sub>a</sub> = 23.0) and HRe(CO)<sub>5</sub> (pK<sub>a</sub> = 21.1<sup>1c</sup>), one might be led to believe that all hydride complexes of the same metal have similar acidities. However, there are substantial differences between the acidity of HMn(CO)<sub>5</sub> (pK<sub>a</sub> = 15.1<sup>1c</sup>) and the acidities of the manganese hydrides in Table II. As discussed above, replacement of one carbonyl in HMn(CO)<sub>5</sub> by a phosphine ligand decreases the acidity of the hydride ligand by 5–6 pK<sub>a</sub> units. Replacement of more than one carbonyl by a polyene ligand leads to further decreases in hydride acidity. For example, replacement of two carbonyls to give the agostic hydride complex (η<sup>3</sup>-C<sub>6</sub>H<sub>9</sub>)(CO)<sub>3</sub>Mn (2) results in a pK<sub>a</sub> of 22.2. The hydride in the benzene complex (η<sup>6</sup>-C<sub>6</sub>H<sub>6</sub>)(CO)<sub>2</sub>MnH (3) has a pK<sub>a</sub> of 26.8, the largest that we have measured. Examination of Scheme I shows clearly how the anions resulting from deprotonation of HMn(CO)<sub>5</sub>, 2, and 3 are related by the substitution of olefin ligands for carbonyls.

The above data indicate a decrease in acidity of approximately 4  $pK_a$  units for each carbonyl ligand replaced in  $\text{HMn}(\text{CO})_5$ , with the acidities of all these manganese hydrides spanning 11.7  $pK_a$  units! The acidity of the agostic hydride complex **2** follows this rule; i.e., it is approximately that expected if the complex were  $\text{HMn}(\text{CO})_3(\eta^4\text{-cyclohexadiene})$ , with a terminal hydride ligand. Apparently the acidity of an agostic hydride, bridging a metal and a carbon atom, does not differ appreciably from that expected for an analogous complex in which the hydride is attached only to the metal.

The  $pK_a$  values of the clusters in Table II allow us to examine the acidities of hydrides that bridge two metals. The trinuclear iron clusters  $(\mu\text{-H})_2\text{Fe}_3(\text{CO})_9(\mu_3\text{-P-}p\text{-C}_6\text{H}_4\text{OCH}_3)$  (**4**),  $(\mu\text{-H})_2\text{Fe}_3(\text{CO})_9(\mu_3\text{-P-}t\text{-Bu})$  (**5**), and  $(\mu\text{-H})\text{Fe}_3(\text{CO})_9(\mu_3\text{-S-C}_6\text{H}_{11})$  (**6**) differ in the nature of the apical group that bridges the three iron atoms, and their acidity is extremely sensitive to changes in this apical group. Variation of the alkyl group of the phosphinidene cap from the anisyl in **4** ( $pK_a = 9.0$ ) to the *tert*-butyl in **5** ( $pK_a = 11.4$ ) changes the  $pK_a$  of these clusters by 2.4 units. Although both **4** and **5** are moderately strong acids, the cyclohexylthio-capped cluster **6** is much weaker ( $pK_a = 16.9$ ).

Polynuclear hydrides are not necessarily more acidic than mononuclear ones. For example,  $\text{H}_2\text{Os}_2(\text{CO})_8$  has a  $pK_a$  only 0.4 unit less than that of  $\text{H}_2\text{Os}(\text{CO})_4$  in acetonitrile.<sup>1a</sup>  $\text{H}_2\text{Os}_3(\text{CO})_{12}$  has a  $pK_a$  only 0.5 unit less than that of  $\text{H}_2\text{Os}(\text{CO})_4$  in methanol.<sup>2b</sup> The hydride ligands in all three compounds are terminal, and the negative charge of the anions arising from deprotonation of  $\text{H}_2\text{Os}_2(\text{CO})_8$  and  $\text{H}_2\text{Os}_3(\text{CO})_{12}$  is probably localized on a single osmium (as has been shown<sup>1a</sup> for  $[\text{HOs}_2(\text{CO})_8]^-$ ). However, if a polynuclear anion has its negative charge delocalized over more than one metal center, we expect it to be more stable than an analogous mononuclear anion; the protonated form of such a delocalized polynuclear anion will be a stronger acid than the protonated form of the corresponding mononuclear anion. We expect a bridging hydride to be more acidic than its terminal counterpart if, and only if, its deprotonated form is a delocalized anion.<sup>13-15</sup> (On the basis of their results with  $\text{H}_4\text{Os}_4(\text{CO})_{12}$  in methanol, Walker, Pearson, and Ford have suggested that for analogous complexes of the same element, bridging hydrides will be more acidic than terminal hydrides.<sup>2b</sup>) A similar situation is familiar in carbanion chemistry: the relatively localized anion resulting from the deprotonation of cycloheptatriene<sup>16</sup> is much less stable than the delocalized

(13) In other words, the structure of the anion formed upon deprotonation, rather than the structure of the hydride, will influence the  $pK_a$ . As bridging hydride ligands usually give delocalized anions upon deprotonation, those hydrides will usually be more acidic than analogous terminal hydride ligands. We predict  $\text{H}_2\text{Fe}_2(\text{CO})_8$ , which has a  $^1\text{H}$  NMR chemical shift<sup>14</sup> suggesting that its hydrides are terminal, to be a much stronger acid than  $\text{H}_2\text{Fe}(\text{CO})_4$  because of the symmetric structure of  $[\text{HFe}_2(\text{CO})_8]^-$ .<sup>15</sup>

(15) (a) Chin, H. B.; Bau, R. *Inorg. Chem.* **1978**, *17*, 2314. (b) Collman, J. P.; Finke, R. G.; Matlock, P. L.; Wahren, R.; Komoto, R. G.; Brauman, J. I. *J. Am. Chem. Soc.* **1978**, *100*, 1119.

one arising from the deprotonation of cyclopentadiene; cycloheptatriene is therefore 20  $pK_a$  units less acidic than cyclopentadiene.

The phosphinidene complex **5** has the same  $pK_a$  as  $\text{H}_2\text{Fe}(\text{CO})_4$  ( $pK_a = 11.4$ ), while **4** ( $pK_a = 9.0$ ) is much more acidic than  $\text{H}_2\text{Fe}(\text{CO})_4$ . However, neither  $\text{H}_2\text{Fe}(\text{CO})_4$  nor any other iron complex with a terminal hydride ligand can usefully be compared with the RP-capped trinuclear hydrides **4** and **5** or with the RS-capped trinuclear hydride **6**.

A better idea of the comparative acidity of bridging and terminal hydrides can be obtained from the series of phosphite-substituted tetranuclear ruthenium hydride clusters  $\text{H}_4\text{Ru}_4(\text{CO})_{12-x}(\text{P}(\text{OCH}_3)_3)_x$  ( $x = 0$ , **7a**;  $x = 1$ , **7b**;  $x = 2$ , **7c**). We have not thoroughly investigated the unsubstituted cluster  $\text{H}_4\text{Ru}_4(\text{CO})_{12}$  (**7a**) since it is only sparingly soluble in acetonitrile. In contrast, the monosubstituted cluster  $\text{H}_4\text{Ru}_4(\text{CO})_{11}(\text{P}(\text{OCH}_3)_3)$  (**7b**) and the disubstituted cluster  $\text{H}_4\text{Ru}_4(\text{CO})_{10}(\text{P}(\text{OCH}_3)_3)_2$  (**7c**) have proven soluble enough to allow measurement of the  $pK_a$  values in Table II (12.4 (1) and 15.4 (2), respectively). If we make the plausible assumption that the unsubstituted **7a** is an even stronger acid than **7b** and **7c**, we can conclude that **7a** is a much stronger acid than  $\text{H}_2\text{Ru}(\text{CO})_4$ :  $pK_a = 18.7$  (2).<sup>1c</sup> As **7a** is a tetranuclear carbonyl hydride and  $\text{H}_2\text{Ru}(\text{CO})_4$  is a mononuclear carbonyl hydride, the comparison is fair and supports the prediction that bridging hydrides should be much stronger acids than their terminal counterparts.

The present acetonitrile data, however, seemed inconsistent with the results reported by Walker, Pearson, and Ford<sup>2b</sup> on **7a-c** in methanol. Our acetonitrile  $pK_a$  values were smaller than their methanol  $pK_a$  values (**7a**, 11.7; **7b**, 14.7; **7c**, >15), implying that these clusters were weaker acids in methanol than in acetonitrile—a result surprising in light of other properties of the two solvents<sup>17</sup> and contrary to previous experience.<sup>18</sup> In the case of **7b**, the only cluster for which both groups had reported exact  $pK_a$  values in their respective solvents, our acetonitrile value (Table II) was 2.3  $pK_a$  units less than their<sup>2b</sup> methanol value.

Walker, Pearson, and Ford<sup>2b</sup> used UV/vis spectroscopy to characterize **7a-c** and the corresponding anions generated by addition of excess sodium methoxide base in methanol solution. They carried out kinetic and thermodynamic measurements in methanol solution using stopped-flow UV/vis spectroscopy at a cluster concentration of ca.  $10^{-5}$  M and methoxide concentrations of  $10^{-2}$ – $10^{-1}$  M. They then derived their apparent rate constants,  $k_f$  and  $k_r$ , from a plot of  $k_{\text{obsd}}$  versus  $[\text{MeO}^-]$ , using eq 3,

$$k_{\text{obsd}} = k_f[\text{MeO}^-] + k_r \quad (3)$$

and used their  $k_f/k_r$  ratio to calculate their equilibrium constants for the deprotonation of **7a-c** and their corre-

(16) (a) Breslow, R. *Acc. Chem. Res.* **1973**, *6*, 393. (b) Wasielewski, M. R.; Breslow, R. *J. Am. Chem. Soc.* **1976**, *98*, 4222. (c) Lowry, T. H.; Richardson, K. S. *Mechanism and Theory in Organic Chemistry*; Harper and Row: New York, 1981, 260.

(17) The Gutmann donor number (DN) for methanol is 19.0, whereas it is 14.1 for acetonitrile (Gutmann, V. *Coordination Chemistry in Non-Aqueous Solutions*; Springer-Verlag: New York, 1968; p 15. Gutmann, V.; Schmid, R. *Coord. Chem. Rev.* **1974**, *12*, 263). Thus solvent methanol is normally a stronger base toward protons than is acetonitrile.

(18) Coetzee<sup>21b</sup> has remarked that "Since acetonitrile is a weaker base than water, all acids are dissociated less in the former solvent than in the latter." A similar statement can be made for acetonitrile and methanol. The acetonitrile  $pK_a$  has been greater than the methanol  $pK_a$  for all hydrides previously examined in both solvents; see Table 3.3 in: Collman, J. P.; Hegedus, L. S.; Norton, J. R.; Finke, R. G. *Principles and Applications of Organotransition Metal Chemistry*; University Science Books: Mill Valley, CA, 1987; p 91.

sponding  $pK_a$  values. They checked their  $pK_a$  value for **7a** by UV/vis study of the equilibration of **7a** in a methanolic veronal/veronate buffer system (pH 12.7).

In an effort to reconcile our results with those of Walker, Pearson, and Ford, we deprotonated **7a** (with ethanolic KOH) and **7b** (with sodium phenolate in THF) and isolated the resulting monoanions as PPN salts. The [PPN][H<sub>3</sub>Ru<sub>4</sub>(CO)<sub>12</sub>] isolated from the deprotonation of **7a** showed the IR and NMR spectra reported for this monoanion in the literature.<sup>7</sup> When we dissolved either isolated **7a** or its isolated monoanion in methanol, we observed the same  $\lambda_{max}$  values (362 and 344 nm, respectively) reported by Walker, Pearson, and Ford<sup>2b</sup> for **7a** and its monoanion in this solvent. We therefore added **7a** to the same methanolic veronal/veronate buffer system used by Walker, Pearson, and Ford and examined the position of the deprotonation equilibrium by IR in the resulting homogeneous solution. Although the reaction took 17 h at room temperature, we observed only the monoanion of **7a**. (The IR spectrum obtained in the veronal/veronate experiment was the same as that observed when the monoanion of **7a** was dissolved in methanol and was virtually identical with that observed for the pure monoanion of **7a** in acetonitrile.) The  $pK_a$  of **7a** in methanol must therefore be much less than the 11.7 reported by Walker, Pearson, and Ford.

The IR and <sup>1</sup>H NMR data in acetonitrile for the monoanion we isolated from the deprotonation of **7b** confirmed that it was [PPN][H<sub>3</sub>Ru<sub>4</sub>(CO)<sub>11</sub>(P(OCH<sub>3</sub>)<sub>3</sub>)]. The spectra of the isolated anion agreed with the IR and NMR spectra we observed in acetonitrile during the partial deprotonation of **7b** by aniline (used above to measure the acetonitrile  $pK_a$  of **7b**). When we dissolved **7b** in methanol, we observed the same  $\lambda_{max}$  (356 nm) reported by Walker, Ford, and Pearson for **7b** in methanol. However, when we dissolved our isolated [PPN][H<sub>3</sub>Ru<sub>4</sub>(CO)<sub>11</sub>(P(OCH<sub>3</sub>)<sub>3</sub>)] in methanol, we observed a  $\lambda_{max}$  (343 nm) significantly different from that (353 nm) found by Walker, Pearson, and Ford when they treated **7b** with excess NaOMe in methanol.

One can imagine two different anions that might be formed by the reaction of a carbonyl cluster such as **7a-c** with methoxide ion. One would of course arise from deprotonation; the other would have a carbomethoxy ligand resulting from methoxide attack on a carbonyl ligand (i.e., [H<sub>4</sub>Ru<sub>4</sub>(CO)<sub>10</sub>(CO<sub>2</sub>Me)(P(OCH<sub>3</sub>)<sub>3</sub>)]<sup>-</sup> from **7b**, reaction 4).

Gross and Ford have observed facile carbomethoxy ligand formation upon reaction of Ru<sub>3</sub>(CO)<sub>12</sub> with NaOCH<sub>3</sub> in methanol and in THF/methanol solutions.<sup>19</sup> Walker, Pearson, and Ford considered carbomethoxy ligand formation and discounted it<sup>2b</sup> because NMR identified [H<sub>3</sub>Ru<sub>4</sub>(CO)<sub>12</sub>]<sup>-</sup> as the only product of the reaction of **7a** with NaOMe in methanol.

However, failure to observe a carbomethoxy anion does not mean that one has not been formed. Such an anion could easily be the kinetic product under the fast conditions of a stopped-flow experiment but not be the thermodynamic product seen in an NMR experiment on the laboratory time scale. The rate constant  $k_1$  ( $8.43 \times 10^1 \text{ M}^{-1} \text{ s}^{-1}$ ) reported by Walker, Pearson, and Ford for the deprotonation of **7b** by methoxide (reaction 5) is surprisingly

large for a deprotonation reaction. For comparison, our preliminary rate constant  $k_2$  for the deprotonation of **7b** by PhND<sub>2</sub> in acetonitrile (reaction 6) is  $5 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$ , slower by more than  $10^5$ .<sup>20,21</sup>

We therefore believe it likely that the reaction observed by Walker, Pearson, and Ford in their stopped-flow experiments is reaction 4 with **7b** and a similar carbomethoxy anion formation reaction with **7a**. The equilibrium constant they derived from their kinetic measurements may be that for methoxide addition (as in reaction 4) instead of that for deprotonation (as in reaction 5).

**Conclusions.** (1) The seven-coordinate hydride complex CpRe(CO)<sub>2</sub>H<sub>2</sub> is not a stronger acid than the six-coordinate hydride complex HRe(CO)<sub>5</sub>. (2) The nature of the ancillary ligands can have a substantial effect on the acidity of transition metal hydride complexes of a given transition metal. In particular, variation of R' in the phosphine ligand of HMn(CO)<sub>5</sub>PR<sub>2</sub>R' and in the phosphinidene complexes ( $\mu$ -H)<sub>2</sub>Fe<sub>3</sub>(CO)<sub>9</sub>( $\mu_3$ -PR') results in a significant change in the acidities of these complexes. (3) The acidity of the agostic hydride in ( $\eta^3$ -C<sub>6</sub>H<sub>9</sub>)Mn(CO)<sub>3</sub> is similar to that expected if it were a terminal hydride. (4) The hydride ligands that bridge two metal centers in H<sub>4</sub>Ru<sub>4</sub>(CO)<sub>12-x</sub>(P(OCH<sub>3</sub>)<sub>3</sub>)<sub>x</sub> ( $x = 0$ , **7a**;  $x = 1$ , **7b**;  $x = 2$ , **7c**) are more acidic than the terminal hydrides in H<sub>2</sub>Ru(CO)<sub>4</sub>, supporting the idea that bridging hydrides are more acidic than terminal ones if the anions arising from the deprotonation of the former are delocalized.

**Acknowledgment.** This research was supported by NSF Grant CHE-8516415. We are grateful to Prof. Gottfried Huttner (Universität Heidelberg) for a generous gift of ( $\mu$ -H)<sub>2</sub>Fe<sub>3</sub>(CO)<sub>9</sub>( $\mu_3$ -P-*t*-Bu), ( $\mu$ -H)<sub>2</sub>Fe<sub>3</sub>(CO)<sub>9</sub>( $\mu_3$ -P-*p*-C<sub>6</sub>H<sub>5</sub>OCH<sub>3</sub>), and ( $\mu$ -H)<sub>2</sub>Fe<sub>3</sub>(CO)<sub>9</sub>( $\mu_3$ -S-*c*-Hex) and to Prof. Maurice Brookhart and S. K. Noh (University of North Carolina) for a generous gift of ( $\eta^6$ -C<sub>6</sub>H<sub>6</sub>)Mn(CO)<sub>2</sub>H and ( $\eta^3$ -C<sub>6</sub>H<sub>9</sub>)Mn(CO)<sub>3</sub>, prepared with the assistance of NIH Grant GM23938. We also thank Prof. Heinrich Vahrenkamp (Universität Freiburg) for helpful discussions and Gary M. Wieber for preliminary experiments. We are particularly grateful to Prof. Peter C. Ford for his comments on a preprint of this paper.

(20) From the methanol  $pK_a$  value cited by Walker, Pearson, and Ford<sup>2b</sup> and their reported  $pK_a$  for **7b**, the equilibrium constant for reaction 5 is  $1.0 \times 10^6$ . From the  $pK_a$  values of **7b** and aniline<sup>21</sup> in acetonitrile, the equilibrium constant for reaction 6 is  $1.4 \times 10^{-2}$ . The ratio of the equilibrium constant for reaction 5 to that for reaction 6 is thus  $7.1 \times 10^8$ , substantially less than the ratio of the rate constants for these two reactions; i.e., the rate ratio is 24 times the equilibrium constant ratio. A similar rate-equilibrium comparison between deprotonation by MeO<sup>-</sup> in MeOH<sup>2b</sup> and deprotonation by aniline in acetonitrile,<sup>1d</sup> for removal of a proton from Os(CO)<sub>4</sub>H<sub>2</sub>, gives a rate ratio ( $3.8 \times 10^9$ ) which is only  $7.5 \times 10^{-9}$  times the equilibrium constant ratio ( $5.1 \times 10^{11}$ ).
