Received January *22, 1993* 

Summary:  $\int Cl_2GaP(SiMe_3)_2 I_2(I)$  has been prepared from the 1:1 reaction of GaCl<sub>3</sub> with P(SiMe<sub>3</sub>)<sub>3</sub>. Thermal decomposition of *1* produces a brown powder which  $contains\,GaP,$  as evidenced by an  $X$ -ray powder pattern and partial elemental analysis. Compound 1 crystallizes<br>in the monoclinic space group  $P2_1/n$  (No. 14) with  $a =$  $i$  9.754(2) Å,  $b = 15.585(5)$  Å,  $c = 9.839(2)$  Å, and  $\beta =$ Chemistry, Keene State<br>

a-P-Ga-Pr

 $96.18(1)$ °, is composed of a planar Ga-P-Ga-Pring, with Ga-P bond distances of 2.378(2) and 2.380(2) A, and  $contains$  exocyclic chlorine and  $S$ iMe<sub>3</sub> ligands. The ring core is a slightly distorted square, with Ga-P-Ga' and P-Ga-P' bond angles of 86.41(7) and 93.59(7)°, respectively. Additionally, 'H NMR confirms that *1* exhibits monomer-dimer equilibrium in solution.

Previous research in our laboratory has proven the utility of silylarsines to prepare compounds containing the gallium-arsenic bond. Using reagents of the general formula  $R_n$ As(SiMe<sub>3</sub>)<sub>3-n</sub> and  $R'_n$ Ga $X_{3-n}$  (n = 0-2), a number of monomeric, dimeric, and trimeric arsinogallanes have been prepared.<sup>1</sup> Subsequent work has explored the more fundamental reactions in the series, namely those between As( $\text{SiMe}_3$ )<sub>3</sub> and  $\text{GaX}_3$  (X = Cl, Br). We have shown that reactions involving these species in a 1:l mole ratio proceed at relatively low temperatures to eliminate Me<sub>3</sub>SiX with concomitant formation of GaAs.<sup>2</sup>

Recent research has applied analogous reaction schemes to gallium-phosphorus systems, yielding both 1:1 adducts and a compound exhibiting mixed bridging of two gallium centers by a phosphorus atom and a halogen.3 Herein we report the isolation and characterization of a remarkably different species resulting from the 1:1 reaction of GaCl<sub>3</sub> and P(SiMe<sub>3</sub>)<sub>3</sub>, [Cl<sub>2</sub>GaP(SiMe<sub>3</sub>)<sub>2</sub>]<sub>2</sub> (1), which through thermolysis yields a GaP-containing powder *(84.8* % purity based on C, H, C1, Ga, P).

#### **Experimental Section**

General Considerations. All manipulations were performed using general Schlenk, drybox, and/or high-vacuum techniques. Solvents (including those used for NMR spectra) were appropriately dried and distilled under argon prior to use. Literature methods were used to prepare  $P(SiMe<sub>3</sub>)<sub>3</sub>$ <sup>4</sup> GaCl<sub>3</sub> was purchased from Alfa Products and purified by sublimation.  ${}^{1}H, {}^{13}C {}^{11}H$ , and  $^{31}P$ {<sup>1</sup>H} NMR spectra were obtained on a Varian XL-300 at 300.0, 75.4, and 121.4 MHz, respectively.  $^{1}$ H and  $^{13}$ C spectra were referenced to TMS via the residual protons or carbons of  $C_6D_6$ or C<sub>7</sub>D<sub>8</sub>. <sup>31</sup>P spectra were referenced to external 80% H<sub>3</sub>PO<sub>4</sub> at 6 0.00 ppm. Mass spectra were obtained on a Hewlett-Packard 5988A GC/MS/DS system. Melting points (uncorrected) were taken in sealed capillaries (Thomas-Hoover Uni-melt). Elemental analysis was performed by  $E + R$  Microanalytical Laboratory, Inc., Corona, NY. The X-ray powder pattern of GaP was recorded at the Crystal Structure Center, Duke University, while the X-ray crystal structure determination of **1** was performed at the New England Molecular Structure Center, Keene State College.

Preparation of  $\text{[Cl}_2\text{GaP(SiMe}_2)_2\text{I}_2(1)$ .  $\text{GaCl}_3(0.2646g, 1.503)$ mmol) in 150 mL of *dry* pentane was placed in a 250-mL roundbottom flask, equipped with a Teflon screw cap and side-arm valve.  $P(SiMe<sub>3</sub>)<sub>3</sub>$  (0.381 g. 1.521 mmol) dissolved in 15 mL of toluene was slowly added to the flask dropwise. The flask was capped and placed in **a** sonicating water bath for 15 h, after which the solvent and volatiles were removed in vacuo, affording a grayish yellow solid. The volatiles were then hydrolyzed with deionized water and titrated with NaOH (0.102 M, 14.40 mL, corresponding to elimination of 1.47 mmol  $(97.8\%)$  of Me<sub>a</sub>SiCl). X-ray-quality crystals of 1 were grown from toluene (0.3714 g, 77.7% yield; decomposes above 220 "C). Anal. Calcd (found) for  $C_6H_{18}Cl_2GaPSi_2$ : C, 22.66 (22.60); H, 5.71 (5.59); Cl, 22.30 (22.06). <sup>1</sup>H NMR:  $\delta$  0.29 [d, 18H, SiMe<sub>3</sub> (monomer)  $J_{P-H} = 6.11$  $Hz$ ], 0.45 [t, 36 H, Si $Me_3$  (dimer)  $J_{P-H}$  = 3.33 Hz]. <sup>13</sup>C{<sup>1</sup>H} NMR: **<sup>6</sup>**2.7-3.0 **[overlappingmultiplet,PSiMe8].** slP{lH] NMR: 6-158.4 *(8).* 

Thermal Decomposition of  $[Cl_2GaP(SiMe<sub>3</sub>)<sub>2</sub>]<sub>2</sub>$  (1).  $[Cl_{2}$ - $GaP(SiMe<sub>3</sub>)<sub>2</sub>$ ]<sub>2</sub> (0.3437 g, 0.540 mmol) was placed in a watercooled sublimator with attached Teflon valve. Under vacuum, the sublimator, which was in a sand bath and was opened to a trap cooled to  $-196$  °C, was slowly warmed over a 3-h period to 300 "C, where it remained overnight. Finally, the powder was annealed for 2 h with a cool flame. Over the course of the decomposition, the initially white material changed to yellow, then orange, and eventually to brown. The brown material was collected in quantitative yield. Collected volatiles were hydrolyzed with deionized water and titrated with NaOH (0.102 M, 18.20mL), correspondingto theelimination of 1.86mmol(85.8%)

of MesSiCl. The brown powder was tightly packed into a thinwalled glass capillary for X-ray powder pattern analysis. Anal. Calcd (found) for GaP: Ga, 69.24 (58.59); P, 30.76 (25.19); C, 0.00 (7.24); **H,** 0.00 (1.22); C1,0.00 (6.88) (Ga:P mole ratio 1.03). The X-ray powder diffraction pattern was identical with that of a bona fide sample of GaP.

Structural Analysis. A single crystal of **1** was mounted in a 0.7-mm thin-walled glass capillary under an inert atmosphere of argon and flame-sealed. Relevant crystallographic data are given in Table I. *All* measurements and calculations were carried out as in previous work.<sup>3</sup> Cell constants and an orientation matrix for data collection, obtained from a least-squares refinement using the setting angles of 20 carefully centered reflections in the range  $30.5^{\circ} < 2\theta < 35.8^{\circ}$ , corresponded to a monoclinic cell. The space group  $P2_1/n$  was defined uniquely by the Laue symmetry and systematic absences *(h0l when h + l*  $\neq 2n$ *, 0k0 when*  $k \neq 2n$ *).* The intensities of three reference reflections, remeasured after every 150 reflections, remained constant throughout data collection, indicating crystal and electronic stability (no decay correction was necessary).

Final fractional atomic coordinates are given in Table **11.**  Selected bond distances and angles are given in Table **111.** A thermal ellipsoid diagram showing the atom labeling scheme for **1** is presented in Figure 1.

*<sup>0</sup>*Primed atoms are related to theunprimed atoms **by** a crystallographic center of symmetry.

Figure **1.** Thermal ellipsoid diagram **(30%** probability level) showing the solid-state conformation and atom-numbering scheme of  $\left[\text{Cl}_2\text{GaP}(\text{SiMe}_3)_2\right]_2(1)$ . Hydrogen atoms have been omitted for clarity.

#### **Results and Discussion**

In an ongoing effort to synthesize possible single-source precursors to group 13-15 semiconductors, dehalosilylations between metal halides and silylpnictides and salt eliminations between metal halides and lithium silylpnictides have been investigated.' Previously, the formation of GaAs from the 1:1 reaction of  $GaCl<sub>3</sub>$  with  $As(SiMe<sub>3</sub>)<sub>3</sub>$  was reported.<sup>2</sup>

As(SINIE<sub>3</sub>)<sub>3</sub> was reported.<sup>2</sup>  
room temp  
GaCl<sub>3</sub> + As(SiMe<sub>3</sub>)<sub>3</sub> 
$$
\rightarrow
$$
 orange powder  $\rightarrow$   
GaAs + 3Me<sub>3</sub>SiCl (1)

This facile reaction proceeds at room temperature to initially yield a white precipitate, which rapidly turns to yellow and finally, upon removal of solvent, to an orange powder. When the orange powder of eq 1 is heated, **GaAs**  of about **95%** purity is obtained. It is unfortunate that no suitable analysis for the orange powder could be obtained, **as** it decomposes rapidly upon standing.

Barron and co-workers have reported the isolation of the product of the analogous reaction in the indiumphosphorus system.<sup>5</sup> The product of the reaction of  $InCl<sub>3</sub>$ with  $P(SiMe<sub>3</sub>)<sub>3</sub>$  is a bright orange powder which has been proposed as an oligomer,  $[Cl_2InP(SiMe<sub>3</sub>)<sub>2</sub>]<sub>x</sub>$  (2), and undergoes thermal decomposition to eliminate Me<sub>3</sub>SiCl, with concomitant formation of InP. However, no X-ray crystal structure of compound **2** has been reported.

It is interesting that the analogous reaction involving  $GaCl<sub>3</sub>$  and  $P(SiMe<sub>3</sub>)<sub>3</sub>$  affords a highly stable and completely characterizable intermediate **(I).** 

The core of **1** consists of a planar Ga-P-Ga-P ring that is a slightly distorted square (Ga-P-Ga'and P-Ga-P' bond angles of  $86.41(7)$  and  $93.59(7)$ °, respectively). The Ga-P and Ga'-P bond lengths of 2.378(2) and 2.380(2) Å, respectively, are the shortest reported to date for compounds having the general formula  $[R_2GaPR'_{2}]_2.^{6-8}$  Cowley and co-workers have reported anumber of these dimeric gallium-phosphorus compounds.<sup>6,7</sup> Of these,  $[t-Bu_2Ga(\mu (C_6H_9)PH1_2$  exhibits the shortest Ga-P bond length of 2.451 Å.<sup>7</sup> Compound 1 is the first reported example of a gallium-phosphorus dimer containing all exocyclic halogen ligands on the metal center. Due to the increased Lewis acidity of the gallium centers from the attached chlorine atoms, the shortened Ga-P distances are reasonable.

Cowley *et al.* have also reported a compound similar to 1,  $(t-\text{BuGa}(\text{Cl})\text{P(H)Ar'}_{2}$  (3),<sup>9</sup> from the 1:1 reaction of  $t$ -BuGaCl with Ar'P(H)Li,  $(Ar' = 2, 4, 6-t$ -Bu<sub>3</sub>C<sub>6</sub>H<sub>2</sub>). Surprisingly, 3 is a chloride-bridged dimer, with exocyclic phosphorus ligands, whereas **1** dimerizes through bridging phosphorus atoms and contains exocyclic halogen ligands. On the basis of purely steric considerations, the chloridebridged dimer may be anticipated, and it is unclear as to

why this does not occur, but it may be due to electronic factors of  $P(H)Ar'$  versus  $P(SiMe<sub>3</sub>)<sub>2</sub>$ .

As for the solution properties of **1,** two separate resonances are observed for the methyl protons in the 'H NMR spectrum of  $\text{[Cl}_2\text{GaP}(\text{SiCH}_3)_3\text{]}_2$ , a downfield triplet **(6** 0.45, **Jp-H** = 3.33 Hz) and an upfield doublet (6 0.29,  $J_{P-H}$  = 6.11 Hz). These resonances suggest that both dimeric and monomeric forms of **1** exist in solution. A variable-temperature study from 20 to 95 °C, in 10 °C increments, begins to demonstrate coalescence, indicating the equilibrium state. In addition, the relative area of the triplet resonance (dimer) to the doublet resonance (monomer) increases with elevated temperature, indicating that the dimeric species is favored at higher temperatures. The l3C NMR spectrum of **1** exhibits an overlapping multiplet in the methyl region, which is indicative of both species. Interestingly, the 31P spectrum exhibits only a singlet, which may actually consist of two overlapping resonances. The dimeric nature of **1** in the gas phase ie established by the parent peak of the direct introduction probe 25 eV electron impact mass spectrum  $(M^+, m/z 632 (69Ga, 35Cl))$ .

Compound 1 has been thermally decomposed at 300 °C to yield a powder containing GaP (84.8% based on C, H, C1, Ga, and P). The relatively low temperature decomposition was not conditionally optimized, nor was the product purified; therefore, the large amount of impurities shown by elemental analysis is not unexpected. On the basis of the high yield of the pyrolyzed volatiles  $(85.8\%)$ and the results of the X-ray powder pattern studies, we conclude that the title compound undergoes facile elimination of its ligands to produce a GaP-containing powder in good yield. Furthermore, the presence of the exocyclic halogen ligands of **1** should provide a viable route for further dehalosilylation and salt elimination reactions to substitute alternative ligands onto the gallium centers.

Acknowledgment. Funding for this research was provided through generous grants from the Office of Naval Research, the Air Force Office of Scientific Research, and the Lord Foundation of North Carolina. J.P.J. acknowledges NSF-RUI Instrument Grant No. 8818307 for establishment of the New England Molecular Structure Center. The assistance of Ray Butcher (X-ray crystallography) at Howard University and George Dubay (mass spectrometry) at Duke University is greatly appreciated.
