Received March 5, 1996[®]

Reaction of the cyclic amides $EN^{t}BuSiMe_{2}N^{t}Bu$ (E = Ge, Sn) with the heterobimetallic complexes [(OC)₃Fe(μ -CO)(μ -Ph₂PXPPh₂)Pt(PR₃)](*Fe*-*Pt*) (X = CH₂, NH; R = phenyl, *p*-tolyl) occurs by selective substitution of the bridging carbonyl ligand and yields the stannylene-

and germylene-bridged complexes $[(OC)_3Fe{\mu-EN^tBuSiMe_2N^tBu}(\mu-Ph_2PXPPh_2)Pt(PR_3)](Fe-Pt)$ (**2a**, X = CH₂, E = Sn, R = Ph; **2b**, X = NH, E = Sn, R = Ph; **2c**, X = CH₂, E = Sn, R

= *p*-tol; **3a**, $X = CH_2$, E = Ge, R = Ph; **3b**, X = NH, E = Ge, R = Ph). When $GeN^tBuSiMe_2N^tBu$ was added in excess to the germylene complex **3a**, the tetranuclear complex [(OC)₃Fe-

 $\{\mu - GeN^tBuSiMe_2N^tBu\}(\mu - dppm)Pt \{GeN^tBuSiMe_2N^tBu\}](Fe - Pt)$ (4) was formed, which is in equilibrium with **3a**. The heterobimetallic Si(OMe)₃-substituted complexes *mer*-[(OC)₃Fe-

 $\{\mu$ -Si(OMe)₂(\dot{O} Me) $\{(\mu$ -dppm) \dot{M} (Me)](Fe-M) (M = Pd, Pt) react with $\dot{E}N^{t}BuSiMe_{2}N^{t}Bu$ (E =

Ge, Sn) by opening of the four-membered Fe-Si-O-M ring to give the complexes mer-

 $[(OC)_{3}Fe{\mu-Si(OMe)_{2}(OMe)}{EN^{t}BuSiMe_{2}N^{t}Bu}{\mu-dppm}M{(Me)}](Fe-M) (5, M = Pt, E =$

Sn; **6**, M = Pd, E = Sn; **7**, M = Pd, E = Ge) which contain a five-membered $\dot{F}e-Si-O-E-\dot{M}$

ring. The expected insertion of the amides $EN^tBuSiMe_2N^tBu$ into the M–Me bond was not observed. The dynamic behavior of these intramolecularly base-stabilized trimetallic germylene and stannylene complexes, which is due to a rapid exchange of the methoxy groups coordinated on E, was investigated by variable-temperature ¹H-NMR spectroscopy. All complexes were characterized by multinuclear NMR spectroscopy, and the solid-state structure of **7** was determined by X-ray diffraction.

Introduction

Heterodinuclear complexes containing a metal–metal bond represent ideal molecules to study the influence of different metal centers on their reactivity, including chemo- and regioselectivity aspects. In addition to metallosite-selective reactions, insertion into the metal– metal bond may occur. It has been shown recently that a Si(OR)₃ group may display novel features in heterometallic complexes which include hemilabile bridging behavior,^{1a–e} migration from one metal center to another^{1a,f} or to organic ligands,^{1a,h–i} or transformation into silylene species.^{1j} On the other hand, cyclic germylenes and stannylenes have been shown to be very versatile reagents toward transition metals² and lead to simple ligand substitutions,^{2f} insertions into metal–carbon bonds,^{2g,h} or more complex reactions such as tin–tin coupling in the tetrametallic chain complex [CpFe-

(CO)₂{SnN^tBuSiMe₂N^tBu}]₂.^{2g} Assuming that poly-

metallic systems associating such silicon and germanium/ tin centered ligands would exhibit interesting new features, we envisaged to combine these two facets in a collaborative approach.

Here we report that metal(II) amides of the type $EN^{t}BuSiMe_{2}N^{t}Bu$ (E = Ge, Sn)^{2a,b} can be used for the systematic buildup of trimetallic compounds containing both main group and transition metals with unprecedented dative interactions between Si(OMe)₃ groups and the metal amides.

Results and Discussion

A. Complexes with a Bridging Stannylene or Germylene Ligand. Synthesis. We began this study with the bimetallic precursor complex $[(OC)_3 \{(MeO)_3Si\}$ - $Fe(\mu$ -dppm)Pt(H)(PPh₃)](Fe-Pt) (1), which contains a terminal hydride ligand on platinum.³ We were interested to see whether treatment of 1 with a slight excess

of SnN^tBuSiMe₂N^tBu in toluene would substitute the PPh₃ ligand or insert into the Pt-H bond. Such insertions of tin amides of the type $[Sn{N(SiMe_3)_2}_2]$ into the M-H bonds of mononuclear complexes have previously been reported by Lappert and Rowe.⁴ However, the outcome of this reaction was very surprising. IR and ³¹P NMR monitoring of the course of the reaction showed that all starting material had been consumed after ca. 45 min, leading to the orange-red trimetallic

cluster [(OC)₃Fe(*u*-SnN^tBuSiMe₂N^tBu)(*u*-dppm)Pt(PPh₃)]-(Fe-Pt) (2a) as the only observable phosphorus-containing species (eq 1). This compound has been fully characterized by elemental analyses and multinuclear NMR techniques (see below).

Formal donor-induced reductive elimination of HSi- $(OMe)_3$ has occurred, a reaction previously observed upon treatment of the related hydrido complex [(OC)₃-

 $\{(MeO)_3Si\}Fe(\mu-dppm)Rh(H)(Cl)\}(Fe-Rh)$ with carbon monoxide.^{5a} Similarly, elimination of HSi(OMe)₃ was observed upon reaction of [HFe{Si(OMe)₃}(CO)₃(η^{1} dppm)] with fac-[Re(CO)₃(THF)(μ -Br)]₂ affording the bromide-bridged complex $[(OC)_3Fe(\mu-dppm)(\mu-Br)Re (CO)_3$.^{5b} In the present case, however, we found no evidence by NMR or IR spectroscopy for the formation of HSi(OMe)₃ in the reaction mixture. We can also rule out the formation of hexamethoxydisilane or tetrameth-

oxysilane, since the singlet resonance observed at δ 3.94 (in C₆D₆) does not correspond with their chemical shifts (commercial samples). Therefore the mechanism of this transformation remains still unclear.

A more rational access to 2 was provided by the selective substitution of the bridging CO ligand of the complexes $[(OC)_3Fe(\mu-CO)(\mu-dppm)Pt(PR_3)](Fe-Pt)$ (R = Ph, p-Tol)⁶ by SnN^tBuSiMe₂N^tBu in toluene under

mild conditions (eq 2).

The orange red clusters **2a,c** have been isolated in high yields and are air-stable for short periods of time. In a similar manner, the yellow bis(diphenylphosphino)amine-bridged cluster 2b was obtained in 74% yield by the reaction of $[(OC)_3Fe(\mu-CO)(\mu-dppa)Pt(PPh_3)](Fe-Pt)^7$

with SnN^tBuSiMe₂N^tBu. The replacement of the dppm bridge by dppa in complex 2b lowers the stability both in the solution and solid state, which may be due to a slow reaction of the N-H group with the tin amide.^{2b} Note that, in contrast to the numerous examples of dppm-bridged bi- and polymetallic complexes, only two

examples of dppa-bridged heterometallics have been described in the literature, to the best of our knowledge.⁸

For comparison, we also examined the reactivity of $[(OC)_{3}Fe(\mu-CO)(\mu-Ph_{2}PXPPh_{2})Pt(PPh_{3})](Fe-Pt)$ toward

the cyclic germanium(II) amide GeNtBuSiMe2NtBu. Upon stoichiometric addition of this germylene reagent, substitution of the bridging CO ligand readily occurred to afford the stable, yellow complexes [(OC)₃Fe-

 $\{\mu$ -GeN^tBuSiMe₂N^tBu} $(\mu$ -Ph₂PXPPh₂)Pt(PPh₃)](Fe-*Pt*) (**3a**, $X = CH_2$; **3b**, X = NH) in nearly quantitative yields. Their spectroscopic data (see below) are very

similar to their tin congeners. Therefore, we assume 3 to be isostructural with 2. In the trimetallic cores of 2 and 3, the three metal centers are mutually connected by metal-metal bonds, conferring to the Pt and Fe centers their usual 16 and 18 e count, respectively.

No reaction took place when the lead(II) amide

PbN^tBuSiMe₂N^tBu was mixed with [(OC)₃Fe(µ-CO)(µdppm)Pt(PPh₃)](*Fe*-*Pt*). However, plumbylene-bridged clusters have been prepared very recently by the reaction of $[Ru_3(CO)_{12}]$ with $[Pb{CH(SiMe_3)}_2]$.⁹

Cluster compounds in which metal(II) amides or related tin species bridge two identical transition metals to form a triangular core were already known. Examples include $[(M\{\mu - E(NR_2)_2\}\CO)_3]$ (M = Pd, Pt; R = SiMe₃), 10a,b [(PPh₃)Pt{ μ -Sn(acac)₂}₃Pt(PPh₃)], 10c [(Ru₃- $(\mu$ -SnR₂)₂(CO)₁₀],^{10d} and [(PPh₃)Pd{ μ -SnN^tBuSiMe₂N-^tBu₃Pd(PPh₃)].²ⁱ Compounds 2 and 3 extend this class of mixed main group-transition metal clusters and represent the first examples where a germylene or stannylene unit bridges different metals connected by

a metal-metal bond. A related Fe-Sn-Pt array was recently established in the μ -SnCl₂ complex [(OC)₃-{(MeO)₃Si}Fe(*u*-dppm)(*u*-SnCl₂)Pt(Cl)(PEt₃)],¹¹ although in this case there was no metal-metal bond between the Pt and Fe centers.

One may ask why the germylene or stannylene ligands exclusively adopt a bridging position in compounds 2 and 3. These ambivalent metal(II) amides possess both a filled σ -donor orbital and a low-lying empty p-orbital and can therefore act as σ -donor and/ or π -acceptor ligands.^{2d,e}

It is known that the π -acceptor ability of σ -donor/ π -acceptor ligands like CO, CS, CNR, or SO₂ generally increases when these ligands are coordinated in a bridging mode. We therefore conclude that it is the electron-donating influence of the three phosphorus ligands (combined with two transiton metals in low oxidation states) which induces a bridging mode for the

the μ -[EN^tBuSiMe₂N^tBu] ligands which can then better evacuate electron density than in a terminal mode.

Spectroscopic Studies. The structure of complexes 2 and 3 could be unambiguously deduced from the combined NMR and IR data as exemplified below for cluster **2a**. The ${}^{31}P{}^{1}H$ NMR spectrum shows a doublet of doublets at δ 83.6 for the iron-bound phosphorus atom, which is strongly coupled $(^{2+3}J(P-P) = 148 \text{ Hz})$ with the platinum-bound dppm phosphorus, which is found at δ 43.5. This signal is further split owing to the presence of the PPh₃ ligand which resonates at δ 41.9 as a doublet of doublets with a typical "cis-coupling" of 13 Hz and a further weak ${}^{3+4}J(P-P)$ coupling of 6 Hz with the dppm phosphorus on iron. All resonances are flanked by ¹⁹⁵Pt satellites with couplings of 80, 2841, and 4491 Hz, respectively. Owing to the presence of the bridging tin nucleus, all resonances show additional sets of ^{119/117}Sn satellites. These ²J(Sn–P) couplings are also found in the ¹¹⁹Sn{¹H} NMR spectrum, which exhibits a ddd pattern centered at δ 615.1. The PPh₃ ligand is only weakly coupled by ca. 45 Hz, whereas the two dppm phosphorus nuclei, which are in a transoid position with respect to tin, are coupled by ca. 130 and 1373 Hz. The ³¹P{¹H} NMR spectrum of **2c** is very similar and is depicted in Figure 1. On the basis of the very different ²J(P²-Sn) and ²J(P³-Sn) coupling constants, one could anticipate that the tin amide ligand bridges the Fe-Pt bond in an unsymmetrical manner, with the larger value being associated with a shorter $Pt-(\mu-Sn)$ distance. However, the almost symmetrically bridging position of the carbene ligand in the related μ -siloxycarbene complex [(OC)₃Fe{ μ -C(Et)OSi(OMe₃)}- $(\mu$ -dppm)Pt(PPh₃)](Fe-Pt) is associated with ²J(P- μ -C) couplings of 14 and 84 Hz.^{1h} By analogy, we therefore assume a rather symmetric bridging position of the tin center between the two transition metals.

A ddd pattern is found in the ¹⁹⁵Pt{¹H} NMR spectrum of **2a**. This signal at δ -3188 displays ¹J(Pt-P) couplings of 2840 Hz (dppm) and 4490 Hz (PPh₃) and a $^{2+3}J(Pt-P)$ coupling of 79 Hz with the iron-bound phosphorus. In addition, a ${}^{1}J(Pt-Sn)$ coupling of 9708 Hz is observed. In the ¹³C{¹H} NMR spectra two doublets are observed for the inequivalent iron carbonyls in a 1:2 ratio at δ 220.1 (see Experimental Section) and 210.8. Both in the ¹³C and ¹H NMR spectrum the SiMe₂ groups appear as two distinct signals due to the bridging bonding mode of the tin atom.

In the ${}^{31}P{}^{1}H$ NMR spectrum of the dppa-bridged derivative **2b** the resonances of the dppa ligand are significantly shifted to lower field. The doublet at δ 122.1 is assigned to the iron-bound phosphorus atom, which is strongly coupled $(^{2+3}J(P-P) = 173 \text{ Hz})$ with the platinum-bound dppa phosphorus at δ 92.6. This signal is further split owing to the presence of the PPh₃ ligand. This latter gives rise to a doublet at δ 41.5 with a cis-coupling of 28 Hz. Whereas the ${}^{1}J(Pt-P^{1})$ coupling for the platinum-bound PPh₃ ligand is similar to that in **2a** (4506 vs 4491 Hz), the ${}^{1}J(Pt-P^{2})$ coupling for the platinum-bound dppa phosphorus is however markedly increased (3235 vs 2841 Hz for 2a). The chemical shift of the ¹⁹⁵Pt nucleus (δ –3260) is not much affected by the nature of the bridging phosphine backbone and appears as a doublet of doublets of doublets with coupling constants of 68, 3235, and 4505 Hz. The NMR data of the dppa-bridged germylene homologue 3b are very similar (see Experimental Section).

The IR spectra of **2** and **3** show three distinct ν (CO) vibrations, as expected for a meridional arrangement of these ligands. The position of these bands is not much influenced by the nature of the bridging Sn or Ge ligand. However, a significant shift to higher wave-numbers is observed for the dppa-bridged derivatives **2b** and **3b**, which may be caused by a lower electron donating ability of the dppa backbone. The solid-state IR spectra of **2b** and **3b** contain a sharp absorption assigned to the N–H vibration (3309 and 3318 cm⁻¹) which is indicative for the absence of hydrogen bonds, otherwise often encountered in dppa complexes.¹²

Reactivity Studies. Reaction of **2a** with 1 equiv of 2,6-dimethylphenyl isocyanide led to quantitative displacement of the tin amide to afford the known isocyanide-bridged complex $[(OC)_3Fe{\mu-CN-xylyl}(\mu-dppm)-$

Pt(PPh₃)](*Fe*-*Pt*).^{3b} Interestingly, GeN^tBuSiMe₂N^tBu substitutes the bridging benzyl isonitrile ligand of [(OC)₃Fe{ μ -CN-benzyl}(μ -dppa)Pt(PPh₃)](*Fe*-*Pt*)⁷ to give **3b.** Attempts to obtain a bis(stannylene) complex remained unsuccessful. Even on addition of a further 2 equiv of $[Sn(N'Bu)_2SiMe_2]$ to a solution of **2a** and gentle heating, only **2a** was recovered. Upon addition of a second 1 equiv of germylene to a toluene solution of **3a**, ³¹P NMR monitoring revealed partial substitution of the PPh₃ ligand with formation of the bis(germylene) complex $[(OC)_3Fe{\mu-GeN^tBuSiMe_2N^t}Bu}$ ^tBu}(μ -dppm)Pt{GeN^tBuSiMe_2N^tBu}] (4) (eq 3).

The existence of an equilibrium between **3a** and **4** is indicated in ³¹P{¹H} NMR by a broad resonance at δ -4.5 due to PPh₃ in rapid exchange with **3a**. This equilibrium can be shifted completely to the right side using a 5-fold excess of GeN^tBuSiMe₂N^tBu. However, attempts to isolate pure **4** failed since **3a** was recovered when excess GeN^tBuSiMe₂N^tBu was removed. We tried also to trap the phosphine by CH₃I; however, a complex mixture of unknown compounds was obtained. The ³¹P-{¹H} NMR spectrum of **4** exhibits a AX pattern centered at δ 78.3 and δ 46.5 for the iron-bound and platinumbound phosphorus atoms, respectively (²⁺³J(P-P) = 150 Hz). The observation of both a ²⁺³J(Pt-P) of 86 Hz and a ¹J(Pt-P) of 2871 Hz supports our assumption that a

Fe–Pt bond is preserved. **B. Complexes with a Cyclic Structure.** The versatility of these cyclic metal(II) amide reagents² led us to consider their reactivity toward heterobimetallic alkyl complexes of the type $[(OC)_3Fe(\mu-Si{OMe})_2-$

(OMe) {(μ -dppm)M(Me)](Fe-M) (M = Pd, Pt), related to **1** but in which the Si(OMe)₃ ligand is bridging between the metals.^{1a,b} The stability of the resulting fourmembered cycle $Fe-Si-O \rightarrow M$ is associated with a lability of the dative $O \rightarrow M$ interaction. This confers a unique hemilabile character to the Si(OMe)₃ ligand and plays a central role for e.g. the migratory insertion of small molecules like isocyanides, CO, and olefins^{1c,d} into the metal-alkyl bond or the catalytic dehydrogenative coupling of stannanes.^{1e}

Insertion of the reactive metal amides $EN^tBuSiMe_2N^-$ ^tBu into the M-C σ -bond was therefore anticipated,

^{(12) (}a) Liehr, G.; Szucsanyi, G.; Ellermann, J. J. Organomet. Chem. **1984**, 265, 95. (b) Steil, P.; Nagel, U.; Beck, W. J. Organomet. Chem. **1989**, 366, 313.

Figure 2. Perspective view and numbering scheme for $mer-[(OC)_3Fe\{\mu-Si(OMe)_2(OMe)\}\{GeN^tBuSiMe_2N^tBu\}-(\mu-dppm)Pd(Me)](Fe-Pd) (7).$

by analogy also with their insertion into the Fe–Me bond of $[CpFe(CO)_2Me]$, which yielded $[CpFe(CO)_2 \{EN^tBuSiMe_2N^tBu\}Me]$.^{2g} However, on the basis of the spectroscopic data, insertion of $EN^tBuSiMe_2N^tBu$ (E = Ge, Sn) into the M–methyl bond of $[(OC)_3Fe(\mu-Si \{OMe)_2(OMe)\}(\mu$ -dppm)M(Me)](*Fe–M*) (M = Pd or Pt) was ruled out, even in the presence of excess reagent and after long reaction times. Instead the trimetallic stannylene or germylene adducts **5–7** were formed in high yields: the reagent has inserted into the dative O \rightarrow M bond to form an unprecedented five-membered ring structure (eq 4). Again, no reaction took place with

the plumbylene PbNtBuSiMe2NtBu reagent.

An X-ray diffraction study was performed on a single crystal of 7 (Figure 2). Unfortunately, extensive decomposition occurred during the data collection, and due to the insufficient data quality, we will not discuss the structural features in detail. Selected bond lengths and angles are listed in Table 1. The structure shown is consistent with IR and multinuclear NMR data at variable temperatures, as exemplified for $[(OC)_3Fe-{\mu-1}]$

Si(OMe)₂(OMe)}{SnN^tBuSiMe₂N^tBu(µ-dppm)Pt}(Me)]-(Fe-Pt) (5). The meridional arrangement of the carbonyls is retained, but a shift of the three ν (CO) vibrations (1947 m, 1884 s, 1848 s) of *ca.* 10 cm⁻¹ to lower wavenumbers results from insertion of the stannylene. The electron-donating effect of the metal amides appears to be larger than their back-bonding abilities. The ³¹P{¹H} NMR data are consistent with this structure (see Experimental Section). In the $^{195}\text{Pt}\{^1\text{H}\}$ NMR spectrum, the dd resonance at δ –2825 shows the expected ¹J(Pt-^{117/119}Sn) couplings in the range of 16 634 and 17 430 Hz, respectively. Compared to the low-field ¹¹⁹Sn chemical shifts of ca. 600 ppm for the μ -stannylene complexes **2a,c**, the ¹¹⁹Sn chemical shifts of **5** and **6** are dramatically high-field shifted at δ 128.7 for **5** and δ 81.2 for **6**.

Proton NMR spectroscopy of **5**–**7** at variable temperatures revealed rapid exchange of the methoxy groups. For **5**, a sharp singlet for the Si(OMe)₃ ligand is observed at δ 3.70, which broadens on lowering the temperature, whereas the other signals remained unaffected. Coalescence was reached at 255 K. Below this temperature, the methoxy resonance gives two distinct signals which are found in a 1:2 ratio at 233 K at δ 3.87 and 3.57, indicating the presence of a rigid five-membered $\overline{\text{Fe}-\text{Si}-\text{O}\rightarrow\text{Sn}-\text{Pt}}$ cycle. Using the Eyring equation, we estimate for **5** a ΔG^{\ddagger} of 51.3 kJ/mol and for the

palladium derivatives **6** and **7** a ΔG^{\ddagger} of 53.6 and 54.7 kJ/mol, respectively. This intramolecular base stabilization may also be responsible for the fact that no insertion reaction into the M-methyl bond was observed.

One may speculate about the validity of a bonding description of complexes 5-7 with a silylene-like bonding of the silyl moiety, base-stabilized by a bridging methoxy group. Such a formalism has been used by Ogino *et al.* to describe the molecular structure of the

fluxional complex [$(\eta$ -C₅Me₅)Fe(CO)GeMe₂OMeSiMe₂], for which rotation about the Fe–Ge bond has been deduced from NMR experiments.¹³

We confidently rule out this description for our compounds which involves rotation around the M-E axis. In the temperature range examined we always observed *two* distinct resonances for the nonequivalent Si–CH₃ groups, which should become identical if the above mechanism were operative. Furthermore, the ²⁹Si NMR chemical shift for the Si(OMe)₃ group of **7** (δ 29.4) is in the usual range for M–Si(OMe)₃ complexes (*e.g.* δ (²⁹Si) 17.6 for [(OC)₃Fe(μ -Si{OMe)₂(OMe)}(μ -dppm)Pd(Me)]-(*Fe*–*Pd*)), whereas that for [η -C₅Me₅)Fe(CO)GeMe₂-OMe-SiMe₂] appears in the low-field region at δ 114.3.³⁴

As noticed above for the $EN^tBuSiMe_2N^tBu$ -bridged clusters **2** and **3**, the germylene derivative **7** is more stable than the stannylene analogues **5** and **6**. Upon standing in solution, the latter gradually loose the tin

amide ligand to regenerate [(OC)₃Fe(µ-Si{OMe)₂(OMe)}-

 $(\mu$ -dppm)M(Me)](*Fe*-*M*), whereas the germylene complex **7** remained unchanged after 2 days in CDCl₃. This may explain our failure to get correct elemental analyses for **5** and **6**.

(C) Attempted Preparation of Fe–Rh Stannylene and Germylene Complexes. We then tried to extend the observations made in eq 4 to a related Fe–Rh complex containing a four-membered ring $Fe-Si-O\rightarrow Rh.^{5a}$ Surprisingly, no reaction took place when [(OC)₃Fe(μ -Si{OMe)₂(OMe)}(μ -dppm)Rh(PPh₃)](*Fe–Rh*) was reacted with an excess of EN^tBuSiMe₂N^tBu.

Even after gentle heating, only the starting materials were recovered. Although stable complexes with Rh– Sn and Rh–Ge bonds have recently been reported from

the reactions of [RhCl(PPh₃)₃] with $EN^tBuSiMe_2N^tBu$,^{2d,i} the strength of the dative MeO \rightarrow Rh interaction appears to prevent adduct formation under ring opening, as found for the related systems **5**–**7**.

Conclusion

We have shown that heterotrimetallic clusters containing both main group and transition metals are obtained in high yields by reaction of cyclic bis(amino)germylenes and -stannylenes with heterobimetallic complexes. The amides adopt exclusively a bridging bonding mode in the clusters 2 and 3 and a terminal base-stabilized bonding mode in complexes 5-7. These heterotrimetallic systems are not reactive (under mild conditions) toward displacement of other ligands, e.g. CO or PPh₃. Future work using more severe reaction conditions or photochemical activation will be required to see whether these compounds can be used for the construction of higher nuclearity clusters. Another aspect which deserves further investigation is the possibility to chemically transform the coordinated metal amides. The present findings demonstrate again the diversity of reaction patterns that may be observed when polymetallic systems are reacted with low-valent main group compounds.

Experimental Section

All reactions were performed in Schlenk-tube flasks under purified nitrogen. Solvents were dried and distilled under nitrogen before use, with tetrahydrofuran over sodium benzophenone ketyl, toluene and hexane over sodium, and dichloromethane from P_4O_{10} . Nitrogen was passed through BASF

R3-11 catalyst and P₄O₁₀ columns to remove residual oxygen or water. Elemental C, H, and N analyses were performed on a Leco CHN 900 elemental analyzer. Infrared spectra were recorded in the $4000-400 \text{ cm}^{-1}$ region on Perkin-Elmer 883 spectrometer. The ¹H, ³¹P{¹H}, ¹¹⁹Sn{¹H}, ²⁹Si-INEPT, and ¹³C{¹H} NMR spectra were recorded at 200.13, 81.01, 74.60, 39.76, and 50.32 MHz, respectively, on a Bruker ACP 200 instrument. Phosphorus chemical shifts were referenced to 85% H₃PO₄ in water and ¹¹⁹Sn chemical shifts to SnMe₄ with downfield shifts reported as positive. ¹⁹⁵Pt chemical shifts were measured on a Bruker ACP 200 instrument (42.95 MHz) and externally referenced to K₂PtCl₄ in water with downfield chemical shifts reported as positive. Unless otherwise stated, NMR spectra were recorded in pure CDCl₃. The reactions were generally monitored by IR in the $\nu(\rm CO)$ region. The presence of 0.5 molecules of toluene in 2a,b has been determined from the ¹H NMR spectrum.

[(OC)₃Fe(µ-SnN^tBuSiMe₂N^tBu))(µ-dppm)Pt(PPh₃)]-

(*Fe*–*Pt*) (2a). Method A. $SnN^{t}BuSiMe_2N^{t}Bu$ (0.21 mmol, 56 μ L) was added slowly to a suspension of [(OC)₃{(MeO)₃Si}-Fe(μ -dppm)Pt(H)(PPh₃)] (1) (220 mg, 0.2 mmol) in C₆D₆ (2 mL) at room temperature. The resulting deep red solution was stirred for 45 min. ³¹P NMR-monitoring showed the presence of **2a** as the only P-containing species in solution. Layering the solution with hexane afforded **2a** in form of orange-yellow microcrystals (0.161 g, 63%).

Method B. A solution of SnNtBuSiMe₂NtBu (0.55 mmol, 160 μ L) in toluene (5 mL) was added slowly to a stirred suspension of $[(OC)_3Fe(\mu-dppm)(\mu-CO)Pt(PPh_3)](Fe-Pt)$ (505) mg, 0.5 mmol) in toluene (10 mL) at room temperature. The clear red mixture was stirred for 15 min and then evaporated under reduced pressure to ca. 4 mL. Addition of hexane yielded 2a as an orange-yellow powder (0.620 g, 92%). (Anal. Si(OMe)₂(OMe)}(µ-dppm)Pd(Me)](Fe-Pd) (1.0 mmol, 768 mg)

in diethyl ether (15 mL) was added dropwise SnNtBuSiMe2Nt-Bu (1.1 mmol. 300 μ L). The reaction mixture was stirred at room temperature for 1 h, and then the volume was reduced to 6 mL. Addition of hexane yielded 6 as a red orange powder, which was washed with hexane and dried under vacuum. IR (KBr): v(CO) 1949 s, 1885 s, 1858 s, v(SiOCH) 2840 w. IR (Et₂O): ν (CO) 1954 m, 1894 s, 1864 s cm⁻¹. ¹H NMR: δ 0.25 (s, 3H, SiMe), 0.28 (s, 3H, SiMe), 0.33 (d, 3H, PdMe, ³J(P-H) = 8.3), 1.22 (s, 18H, ^tBu), 3.53 (t, 2H, PCH₂P, ²J(P-H) = 10.4), 3.75 (s, 9H, Si(OMe)₃), 7.19–7.53 (m, 20H, C_6H_5). ³¹P{¹H} NMR: δ 32.25 (d, P¹(Pd-P), ²⁺³ J(P¹-P²) = 113, ² J(P⁻¹¹⁷Sn) $= 3417, {}^{2}J(P-{}^{119}Sn) = 3550), 70.9 (d, P{}^{2}(Fe-P), {}^{3+4}J(P-Sn) =$ 195). ²⁹Si-INEPT NMR: δ 2.68 (d, SiMe₂, ⁴J(Si-P¹) = 1.9, ${}^{2}J(Si-Sn) = 23.6), 26.8 \text{ (dd, SiOMe, } {}^{2}J(P^{2}-Si) = 34.1, {}^{4}J(P^{2}-Si) = 34$ Si) = 3.6). ¹¹⁹Sn{¹H} NMR: δ 81.2 (dd, ²*J*(P¹-Sn) = 3554, $^{3+4}J(P^2-Sn) = 197$ Hz).

 $[(OC)_{3}Fe{\mu-Si(OMe)_{2}(OMe)}{GeN^{B}uSiMe_{2}N^{B}u}{\mu-dppm}Pd(Me)](Fe-Pd)$ (7). It was prepared similarly to 6, using $[(OC)_{3}Fe{\mu-Si(OMe)_{2}(OMe)}(\mu-dppm)Pd(Me)](Fe-Pd)$

(1.0 mmol, 768 mg) and GeN^tBuSiMe₂N^tBu (1.1 mmol, 300 μ L). The complex was isolated in form of nearly colorless thin plates from a cold Et₂O/hexane mixture (0.697 g, 67%). (Anal. Found: C, 48.92; H, 5.91; N, 2.65. Calc for C₄₂H₅₈N₂O₆P₂-FePdSi₂Ge (M = 1039.86): C, 48.51; H, 5.62; N, 2.69). IR (KBr): ν (CO) 1947 s, 1878 s, 1851 s, ν (SiOCH) 2831 w. IR (toluene): ν (CO) 1947 m, 1881 s, 1850 s cm⁻¹. ¹H NMR: δ 0.30 (s, 3H, SiMe), 0.35 (s, 3H, SiMe), 0.40 (d, 3H, PdMe, ³*J*(P-

Reactions of Fe-Pt and Fe-Pd Complexes

H) = 8.4), 1.24 (s, 18H, ^tBu), 3.46 (t, 2H, PCH₂P, ²*J*(P–H) = 10.3), 3.73 (s, 9H, Si(OMe)₃), 7.23–7.56 (m, 20H, C₆H₅). ³¹P-{¹H} NMR: δ 31.1 (d, P¹(Pd–P), ²⁺³*J*(P¹–P²) = 118), 72.4 (d, P²(Fe–P)). ²⁹Si-INEPT NMR: δ 4.07 (d, SiMe₂, ⁴*J*(Si–P¹) = 3.6), 29.36 (dd, SiOMe, ⁴*J*(P¹–Si) = 4.4, ²*J*(P²–Si) = 35). ¹³C-{¹H} NMR: δ 2.5 (d, 1C, SiMe, ⁵*J*(P–C) = 1), 4.7 (s, 1C, SiMe), 6.1 (d, 1C, PdMe, ²*J*(P–C) = 3), 33.8 (s, 6C, C–*Me*), 38.1 (t, 1C, PCH₂P), 50.4 (s, 3C, SiOMe), 51.0 (s, 2C, N–*C*), 127.8 - 136.2 (m, 24C, C₆H₅), 211.1 (d, 2C, CO, ²*J*(P–C) = 25), 214.9 (d, 1C, CO, ²*J*(P–C) = 14 Hz).

Crystallographic Data for Complex 7: Crystal system, triclinic; space group, $P\overline{1}$; a = 10.704(10), b = 20.53(2), c = 25.76(3) Å; $\alpha = 68.88(4)$, $\beta = 79.33(4)$, $\gamma = 80.20(4)^{\circ}$; V = 5155-(9) Å³; Z = 4; d(calc) = 1.340 g/cm³. Data were collected at 293 K on a Siemens Stoe AED 2 diffractometer using graphite-monochromated Mo K α radiation (0.710 73 Å). Intensities were collected from $1.58-22.52^{\circ}$ in Θ , using the ω - Θ scan

mode: total number of unique data, 8263; number of observed unique data, 5298; final R_1 ($I > 2\sigma(I)$) = 0.1318; w R_2 = 0.3770.

Acknowledgment. We are very grateful to the Deutsche Forschungsgemeinschaft for financial support, to the CNRS, the Ministère de l'Enseignement Supérieur et de la Recherche, the Ministère des Affaires Etrangères (Paris), and the DAAD (PROCOPE project) for support, and to DEGUSSA AG for a generous gift of Pd and Pt salts.

Supporting Information Available: Tables of crystallographic data, atom parameters, thermal parameters, and bond distances and angles (10 pages). Ordering information is given on any current masthead page.
