Vinyl C–H Activation Reactions of Vinyl Esters
Mediated by B(C₆F₅)₃

Summary: B(C₆F₅)₃ reacts with simple vinyl esters by electrophilic addition to the C=C bond and subsequent proton transfer and elimination of C₆F₅H to yield the chelated vinylborane products (C₆F₅)₂B{κ²-CH=CHOC(=O)R} (R = Me, Ph).

Tris(perfluorophenyl)borane, B(C₆F₅)₃,¹ has been used extensively as an activator for metallocene and other single-site olefin polymerization catalysts.² In this application, B(C₆F₅)₃ abstracts a hydrocarbyl group from an L_nMR₂ precursor to form an active [L_nMR][RB(C₆F₅)₃] ion pair. B(C₆F₅)₃ has also been used as a Lewis acid catalyst for the hydrosilation of carbonyl compounds,³ silylation and reduction of alcohols and cleavage of ethers with silanes,⁴ addition of silyl enol ethers to carbonyl compounds and other electrophiles,⁵ hydrostannation of allenes,⁶ and a variety of other reactions.⁷ The Lewis acidity of B(C₆F₅)₃ is comparable to that of BF₃,^{1b} and XB(C₆F₅)₃⁻ anions are generally more resistant to

degradation by X⁻ transfer than are XBF₃⁻ anions.⁸ Here we describe an unusual reaction in which electrophilic addition of B(C₆F₅)₃ to the C=C bond of vinyl esters and subsequent B–C₆F₅ bond cleavage results in net vinylic C–H activation and the formation of vinylborane products.

The new chemistry is summarized in Scheme 1.⁹ At 23 °C in benzene-*d*₆, B(C₆F₅)₃ reacts immediately with vinyl acetate to form the carbonyl adduct CH₂=CHOC(=O)B(C₆F₅)₃Me (**1a**). Complex **1a** was characterized by multinuclear NMR but was not isolated. Key NMR parameters for **1a** include a low-field ¹³C carbonyl resonance at δ 179.9 (vs 167.0 for free vinyl acetate), ¹⁹F NMR resonances at δ –133.1, –151.6, –161.9, and an ¹¹B NMR resonance at δ 15.6 characteristic of a four-coordinate B(C₆F₅)₃L species.¹⁰ These data are very similar to the data for the ethyl benzoate adduct EtOC(=O)B(C₆F₅)₃Ph (δ_C, 173.5; δ_B, 19.2) reported by Piers

(9) Characterization data for new compounds are given in the Supporting Information.

Scheme 1

et al.^{10a} Adduct **1a** is stable at room temperature in benzene-*d*₆ for at least 48 h. However, heating a benzene-*d*₆ solution of **1a** at 60 °C for 12 h yields a 1/1 mixture of C₆F₅H (**2**) and the chelated vinylborane (C₆F₅)₂B{κ²-CH=CHOC(=O)Me} (**3a**) with a conversion of 93%. Compounds **2** and **3a** were characterized by multinuclear NMR and GC-MS and, for **3a**, elemental analysis. Key NMR parameters for **3a** include (i) a ¹³C carbonyl resonance at δ 196.0, characteristic of carbonyl oxygen coordination to a Lewis acid, (ii) two doublets for the *cis*-vinyl CH groups (*J* = 4.0 Hz) in the ¹H spectrum, and (iii) ¹⁹F resonances at δ -136.2, -155.5 and -163.4 and a ¹¹B resonance at δ 5.2, consistent with a four-coordinate RB(C₆F₅)₂L species. Very similar NMR data (¹⁹F, δ -134.5, -158.1, -163.8; ¹¹B, δ 6.8) were reported for (C₆F₅)₂B{κ²-CH₂(CH₂)₃C(=O)OEt}, in which the ester carbonyl group is coordinated to boron.¹¹

A plausible mechanism for this reaction is shown in Scheme 1. The key steps leading to **2** and **3a** are electrophilic attack of B(C₆F₅)₃ at the C=C bond to generate the zwitterionic intermediate **4a**, proton trans-

fer to the carbonyl oxygen to generate the carbonyl-protonated species **5a**, and protonolysis of a B-C₆F₅ bond.

The reaction of vinyl acetate with B(C₆F₅)₃ to produce **2** and **3a** is much faster in CD₂Cl₂ than in benzene-*d*₆, and in this case intermediate **5a** can be detected by NMR. Monitoring the reaction in CD₂Cl₂ by NMR at 23 °C revealed the initial formation of carbonyl adduct **1a**, subsequent conversion to **5a**, and ultimate formation of **2** and **3a**. The **1a/5a/3a** ratio was 1.0/0.72/0.27 after 5 h, and the conversion to **2** and **3a** (1/1 ratio) was complete after 30 h. Key NMR parameters for **5a** include (i) a ¹H resonance at δ 12.87 and a ¹³C carbonyl resonance at δ 199.1, which are correlated in the 2D-HMBC spectrum and are assigned to the protonated carbonyl group,¹² (ii) two coupled doublets (*J* = 4.4 Hz) in the ¹H spectrum, which are correlated in the COSY spectrum and are assigned to the *cis*-vinyl CH groups, and (iii) ¹⁹F resonances at δ -134.6, -156.7, and -163.8 and a ¹¹B resonance at δ 2.15, for the (vinyl)B(C₆F₅)₃⁻ unit. The close proximity of the protonated carbonyl group and the methyl group was established by a ¹H-¹H NOESY spectrum, which exhibited a strong cross-peak between the O-H (δ 12.87) and the Me (δ 2.47) resonances. The acceleration of the reaction in CD₂Cl₂ versus benzene-*d*₆ is ascribed to stabilization of the zwitterionic intermediates **4a** and **5a** by the more polar solvent.

Similarly, vinyl benzoate reacts with B(C₆F₅)₃ in CD₂-Cl₂ at room temperature to generate **5b** in 50% yield after 15 min along with 50% of unreacted starting materials (Scheme 1). After 12 h, 93% conversion to a 1/1 mixture of **2** and **3b** was observed.¹³ The NMR data for **3b** and **5b** are similar to the data for **3a** and **5a**.⁹ To corroborate the structure of intermediates **5a,b** and in particular to confirm the presence of a protonated carbonyl group in these species, the 1/1/1 mixture of **5b**, vinyl benzoate, and B(C₆F₅)₃ generated at 50% conversion was treated with Proton Sponge (1,8-bis(dimethyl-amino)naphthalene, PS). An immediate reaction occurred to produce [PS-H][{*cis*-(C₆F₅)₃BCH=CHOC(=O)B(C₆F₅)₃}Ph}] ([PS-H][**6b**]) quantitatively (along with unreacted vinyl benzoate). The unreacted B(C₆F₅)₃ present in the solution reacts with deprotonated **5b** to form **6b**⁻. Key NMR parameters for **6b**⁻ include (i) a low-field ¹³C carbonyl resonance at δ 196.4, (ii) two sets of ¹⁹F signals for the two four-coordinate -B(C₆F₅)₃ groups, and (iii) a broad ¹¹B signal centered at δ -1.5 for the two B centers. The ¹H NMR spectrum of [PS-H][**6b**] contains a signal at δ 19.49 for the PS-H⁺ bridging proton which is correlated with the NMe₂ resonance at δ 3.14 in the COSY spectrum.¹⁴

Vinyl esters are not generally susceptible to electrophilic attack at the vinyl group, due to the weak ability

(12) The HMBC (heteronuclear multiple-bond correlation) experiment enables determination of two- and three-bond ¹H-¹³C connectivity: Bax, A.; Summers, M. J. *J. Am. Chem. Soc.* **1986**, *108*, 2093.

(13) Compounds **2** and **3b** (1/1 ratio) are generated quantitatively by heating a CD₂Cl₂ solution of B(C₆F₅)₃ and vinyl benzoate to 80 °C for 3 h (sealed tube). In benzene-*d*₆ solution, 86% conversion to **2** and **3b** is observed after 5 days at 80 °C.

of the $-\text{OC}(=\text{O})\text{R}$ group to stabilize the carbocation intermediate. Thus, while vinyl ethers undergo facile cationic polymerization, vinyl esters do not.¹⁵ Nevertheless, electrophilic attack at the $\text{C}=\text{C}$ bond of vinyl esters has been established in several cases. For example, Noyce and Pollack showed by kinetic, substituent effect, and solvent isotope effect studies that acid hydrolysis of vinyl esters proceeds by two competing mechanisms: (i) initial protonation at the carbonyl oxygen followed by H_2O attack and collapse to products ($\text{A}_{\text{AC}2}$ mechanism), analogous to the mechanism for saturated esters, or (ii) initial protonation at the $\text{C}=\text{C}$ bond followed by H_2O attack and collapse to products ($\text{A}_{\text{SE}2}$ mechanism), analogous to the normal mechanism for vinyl ethers.¹⁶ The latter process is important under highly acidic conditions and when the carbocation resulting from protonation at carbon is strongly stabilized by substituents (e.g. α -acetoxy styrenes). Landgrebe showed by NMR H/D exchange studies that isopropenyl acetate undergoes fast reversible protonation at the $\text{C}=\text{C}$ bond in concentrated $\text{H}_2\text{SO}_4/\text{D}_2\text{SO}_4$ solution.^{17–19} In the present case, the kinetic product of the reaction of $\text{B}(\text{C}_6\text{F}_5)_3$ with vinyl acetate is the carbonyl adduct, but formation of

the vinylborane product derived from $\text{C}=\text{C}$ attack is driven by the irreversible protonolysis of the $\text{B}-\text{C}_6\text{F}_5$ bond.

The formation of **5a,b** from $\text{B}(\text{C}_6\text{F}_5)_3$ and the appropriate vinyl ester is a net electrophilic substitution of a vinyl hydrogen by a $\text{B}(\text{C}_6\text{F}_5)_3$ group. This reaction bears some similarity to the reaction of metal cyclopentadienyl complexes with electrophilic boranes to yield $\text{M}\{\text{C}_5\text{H}_4\text{B}^-\text{X}_3\}$ products.²⁰ For example, the reaction of the zirconacyclopentadiene complex $\text{Cp}_2\text{Zr}(\text{C}_4\text{Me}_4)$ with $\text{B}(\text{C}_6\text{F}_5)_3$ yields $\text{Cp}\{\eta^5\text{-C}_5\text{H}_4\text{B}^-(\text{C}_6\text{F}_5)_3\}\text{Zr}^+(\sigma\text{-CMe}=\text{CMe}=\text{CHMe})$, presumably via electrophilic attack of $\text{B}(\text{C}_6\text{F}_5)_3$ at a Cp ligand to generate $\text{Cp}\{(1\text{-exo-B}^-(\text{C}_6\text{F}_5)_3\text{-cyclopentadiene})\text{Zr}^+(\text{C}_4\text{Me}_4)\}$ followed by protonolysis of a $\text{Zr}-\text{C}$ σ bond by the endo $\text{C}-\text{H}$ group.^{20b}
